Index of smartBASIC Commands .........................................................................................................258
1. **INTRODUCTION**

**Documentation Overview**

This RM1xx Extension Functionality user guide provides detailed information on RM1xx-specific *smartBASIC* extensions which provide a high level managed interface to the underlying LoRa device and Bluetooth stack in order to manage the following:

- Joining a LoRa gateway and transmitting/receiving data payload
- Link checking on LoRa connection
- Managing LoRa sleep intervals and reading chipset registers
- GATT table – Services, characteristics, descriptors, advert reports
- GATT server/client operation
- BLE Advertisments and connections
- BLE security and bonding
- Attribute encoding and decoding
- Power management
- Wireless status
- Events related to the above

Please refer to the *smartBASIC* core reference manual for more details on common functionality that exists in all platforms that offer *smartBASIC*.

**What Does a LoRa/BLE Module Contain?**

Laird’s *smartBASIC*-based LoRa/BLE modules are designed to provide a complete wireless processing solution and contain the following:

- A highly integrated radio with an integrated antenna (external antenna options are also available)
- BLE Physical and Link Layer
- Higher level stack
- Multiple GPIO and ADC
- Wired communication interfaces such as UART, I2C, and SPI
- A *smartBASIC* run-time engine
- Program-accessible flash memory which contains a robust flash file system exposing a conventional file system and a database for storing user configuration data
- Voltage regulators and brown-out detectors

For simple end devices, these modules can completely replace an embedded processing system.

The following block diagram ([Figure 1](#)) illustrates the structure of the BLE + LoRa *smartBASIC* module from a hardware perspective on the left and a firmware/software perspective on the right.
2. **INTERACTIVE MODE COMMANDS**

Interactive mode commands allow a host processor or terminal emulator to interrogate and control the operation of a *smart* BASIC-based module. Many of these emulate the functionality of AT commands. Others add extra functionality for controlling the filing system and compilation process.

**Syntax**  Unlike commands for AT modems, a space character must be inserted between AT, the command, and subsequent parameters. This allows the *smart* BASIC tokeniser to efficiently distinguish between AT commands and other tokens or variables starting with the letters AT.

```
Example:
AT I 3
```

The response to every Interactive mode command has the following form:

```markdown
<linefeed character> response text <carriage return>
```

This format simplifies the parsing within the host processor. The response may be one or multiple lines. Where more than one line is returned, the last line has one of the following formats:

- `<lf>` for a successful outcome, or
- `<lf>01<tab> hex number <tab> optional verbose explanation <cr>` for failure.

**Note:** In the case of the 01 response, the `<tab>optional verbose explanation` is missing in resource constrained platforms like the RM1xx modules. The *verbose explanation* is a constant string and since there are over 1000 error codes, these verbose strings can occupy more than 10 kilobytes of flash memory.
The hex number in the response is the error result code consisting of two digits which can be used to help investigate the problem causing the failure. Rather than provide a list of all the error codes in this manual, you can use UWTerminal to obtain a verbose description of an error when it is not provided on a platform.

To get the verbose description, click the BASIC tab (in UWTerminal) and, if the error value is hhhh, enter the command ER 0xhhhh and note the 0x prefix to hhhh. This is illustrated in Error! Reference source not found..

![UWTerminal screenshot]

*Figure 2: Optional verbose explanation*

You can also obtain a verbose description of an error by highlighting the error value, right-clicking, and selecting **Lookup Selected ErrorCode** in the Terminal window.

If you get the text UNKNOWN RESULT CODE 0xHHHH, please contact Laird for the latest version of UWTerminal.

**AT I ATI ATI ATI**

Provided to give compatibility with the AT command set of Laird’s standard Bluetooth modules.

**AT I num**

**COMMAND**

| Returns                  | \n10tMM\tInformation\r  
|                         | \n00\r               |
| Where                   | \n = linefeed character 0x0A  
|                         | \t = horizontal tab character 0x09  
| MM = a number (see below) | Information = sting consisting of information requested associated with MM  
|                         | \r = carriage return character 0x0D |

**Arguments**

<table>
<thead>
<tr>
<th>num</th>
<th>Integer Constant – A number in the range 0 to 65,535. Currently defined numbers are:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Name of device</td>
</tr>
<tr>
<td>3</td>
<td>Version number of the module firmware</td>
</tr>
<tr>
<td>4</td>
<td><strong>MAC address</strong> in the form TT AAAAAAAAAAAAAA</td>
</tr>
<tr>
<td>5</td>
<td>Chipset name</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>6</td>
<td>Flash File System size stats (data segment): Total/Free/Deleted</td>
</tr>
<tr>
<td>7</td>
<td>Flash File System size stats (FAT segment): Total/Free/Deleted</td>
</tr>
<tr>
<td>12</td>
<td>Last error code</td>
</tr>
<tr>
<td>13</td>
<td>Language hash value</td>
</tr>
<tr>
<td>16</td>
<td>NvRecord Memory Store stats: Total/Free/Deleted</td>
</tr>
<tr>
<td>33</td>
<td>BASIC core version number</td>
</tr>
<tr>
<td>601</td>
<td>Flash File System: Data Segment: Total Space</td>
</tr>
<tr>

</tr>
<tr>
<td>2000...2999</td>
<td>See SYSINFO() function definition</td>
</tr>
</tbody>
</table>

**Interactive Command**: Yes

Any other number currently returns the manufacturer’s name.

For ATi4, the TT in the response is the type of address as follows:

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Public IEEE format address</td>
</tr>
<tr>
<td>01</td>
<td>Random static address (default as shipped)</td>
</tr>
<tr>
<td>02</td>
<td>Random Private Resolvable (used with bonded devices) – <strong>not currently available</strong></td>
</tr>
<tr>
<td>03</td>
<td>Random Private Non-Resolvable (used for reconnections) – <strong>not currently available</strong></td>
</tr>
</tbody>
</table>

**Note**: Please refer to the Bluetooth specification for a further description of the types.

This is an Interactive mode command and **must** be terminated by a carriage return for it to be processed.

```
\Example:
AT i 3
10 3 2.0.1.2
00
AT i 4
10 4 01 D31A920731B0
```

AT i is a core command.
The information returned by this Interactive command can also be useful from within a running application and so a built-in function called SYSINFO(cmdId) can be used to return exactly the same information and cmdid is the same value as used in the list above.

**AT+CFGEX**

**COMMAND**

AT+CFGEX is used to set a non-volatile configuration key with a string. The syntax of this command is defined in the smartBASIC Core Functionality Manual.

The following configuration key IDs are specific to the RM1xx module.

<table>
<thead>
<tr>
<th>Key ID</th>
<th>Definition</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1009</td>
<td>ChannelsMask</td>
<td>Sets the ChannelsMask. Only valid for the RM191. See the Setting RM191 ChannelsMask section below</td>
</tr>
<tr>
<td>1010</td>
<td>AppEui</td>
<td>Application Identifier – 8 Bytes/16 Hex Characters</td>
</tr>
<tr>
<td>1011</td>
<td>DevEui</td>
<td>End Device Identifier – 8 Bytes/16 Hex Characters</td>
</tr>
<tr>
<td>1012</td>
<td>AppKey</td>
<td>Application Key – 16 Bytes/32 Hex Characters</td>
</tr>
<tr>
<td>1013</td>
<td>NwkSKey</td>
<td>Network Session Key – 16 Bytes/32 Hex Characters</td>
</tr>
<tr>
<td>1014</td>
<td>AppSKey</td>
<td>Application Session Key – 16 Bytes/32 Hex Characters</td>
</tr>
<tr>
<td>1015</td>
<td>DevAddr</td>
<td>End device Address – 8-character Hex string</td>
</tr>
</tbody>
</table>

The at+cfgex command returns an invalid key error (7312) if an invalid Key id is entered or the length of the entered string is incorrect for that specific Key id.

The new config value is only available for use after a system reset.

**Note:** The NwkSKey, AppSKey, and AppKey values are write-only. These values cannot be read back using the at+cfgex xxxx? command.

Prior to firmware versions 17/18.4.1.0 the Key Ids in the table above were in the range of 1000 – 1005 instead of the new range of 1010-1015.

**AT&F**

**COMMAND**

AT&F provides facilities for erasing various portions of the module’s non-volatile memory.

**AT&F integermask**

<table>
<thead>
<tr>
<th>Returns</th>
<th>OK if file successfully erased.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>Integer corresponding to a bit mask or the “*” character</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>Yes</td>
</tr>
</tbody>
</table>
The mask is an additive integer mask, with the following meaning:

<table>
<thead>
<tr>
<th>Mask</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0000xxxx</td>
<td>See core user manual</td>
</tr>
<tr>
<td>0x00010000</td>
<td>Erase the BLE bonding database</td>
</tr>
<tr>
<td>*</td>
<td>Erases all data segments</td>
</tr>
</tbody>
</table>

If an asterisk is used in place of a number, then the module is configured back to the factory default state by erasing all flash file segments.

This is an Interactive Mode command and MUST be terminated by a carriage return for it to be processed.

```
AT&F 0x10000 'delete the BLE bonding database (AT+BTD* also does it)
AT&F * 'delete all data segments
```

AT&F is a core command with extensions.

**AT + BTD ***

**COMMAND**

Deletes the bonded device database from the flash.

**AT + BTD**

<table>
<thead>
<tr>
<th>Returns</th>
<th>\n00\r</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>None</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>Yes</td>
</tr>
</tbody>
</table>

This is an Interactive Mode command and MUST be terminated by a carriage return to be processed.

**Note:** The module self-reboots so that the bonding manager context is also reset.

**Examples:**

```
AT+BTD*
```

AT+BTD* is an extension command.

**AT + MAC 12 hex digit mac address**

**COMMAND**

This is a command that is successful one time as it writes an IEEE MAC address to non-volatile memory. This address is then used instead of the random static MAC address that comes preprogrammed in the module.

**Notes:**
- If the module has an invalid licence then this address is not visible.
- If the address 000000000000 is written then it is treated as invalid and prevents a new address from being entered.
AT + MAC “12 hex digits”

<table>
<thead>
<tr>
<th>Returns</th>
<th>\n00\r or \n01 192A\r</th>
</tr>
</thead>
<tbody>
<tr>
<td>Where the error code 192A is NVO_NVWORM_EXISTS. This means that an IEEE MAC address already exists, which can be read using the command AT I 24.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
<th>A string delimited by “” which shall be a valid 12 hex digit MAC address that is written to non-volatile memory.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Interactive Command</th>
<th>Yes</th>
</tr>
</thead>
</table>

This is an Interactive mode command and MUST be terminated by a carriage return for it to be processed.

**Note:** The module self-reboots if the write is successful. Subsequent invocations of this command generate an error.

```
'Examples:
AT+MAC "008098010203"
```

AT+MAC is an extension command

**AT + BLX**

**COMMAND**

This command is used to stop all radio activity (adverts or connections) when in interactive mode. It is particularly useful when the virtual serial port is enabled while in interactive mode.

<table>
<thead>
<tr>
<th>AT + BLX</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Returns</strong></td>
</tr>
<tr>
<td><strong>Arguments</strong></td>
</tr>
<tr>
<td><strong>Interactive Command</strong></td>
</tr>
</tbody>
</table>

This is an Interactive Mode command and MUST be terminated by a carriage return for it to be processed.

**Note:** The module self-reboots so that the bonding manager context is also reset.

```
'Examples:
AT+BLX
```

AT+BLX is an extension command.
3. Core Language Built-in Routines

Core Language built-in routines are present in every implementation of smart BASIC. These routines provide the basic programming functionality. They are augmented with target specific routines for different platforms which are described in the next chapter.

Result Codes

Some of these built-in routines are subroutines and some are functions. Functions always return a value and, for some of these functions the value returned is a result code, indicating success or failure in executing that function. A failure may not necessarily result in a run-time error (see GetLastError() and ResetLastError()), but may lead to an unexpected output.

Being able to see the cause of a failure helps with the debugging process. If you declare an integer variable such as rc and set its value to your function call, after the function is executed you can print rc and see the result code. For this to be useful, it must be in hexadecimal form; prefix your result code variable with INTEGER.H' when printing it. You can also save some memory by printing the return value from the function directly without the use of a variable.

highlight the last four characters of the result code in UwTerminal and select Lookup Selected ErrorCode (Figure 3).

```
//Example :: ResultCodes.sb (See in RM1xxCodeSnippets.zip)
DIM cB,nItems,rc,s$

rc=CircBufItems(cB,nItems)
PRINT INTEGER.H’rc

PRINT "\n";  //New line

//Printing return value directly
PRINT INTEGER.H’CircBufItems(cB,nItems)

//To remove the leading zeros
SPRINT #s$, INTEGER.H’CircBufItems(cB,nItems)
StrShiftLeft(s$,4) : PRINT s$
```

Figure 3: Lookup Selected ErrorCode
Information Routines

SYSINFO

FUNCTION

Returns an informational integer value depending on the value of `varId` argument.

SYSINFO(varId)

<table>
<thead>
<tr>
<th>ID</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Device ID. For the RM1xx module, the value is 0x42460600</td>
</tr>
</tbody>
</table>
| 3    | Version number of the module firmware. For example, W.X.Y.Z is returned as a 32-bit value made up as follows: 

\[(W<<26) + (X<<20) + (Y<<6) + (Z)\]

where Y is the build number and Z is the sub-build number |
| 33   | BASIC core version number                                                                     |
| 601  | Flash File System: Data Segment: Total Space                                                  |
| 602  | Flash File System: Data Segment: Free Space                                                   |
| 603  | Flash File System: Data Segment: Deleted Space                                                |
| 611  | Flash File System: FAT Segment: Total Space                                                   |
| 612  | Flash File System: FAT Segment: Free Space                                                   |
| 613  | Flash File System: FAT Segment: Deleted Space                                                |
| 631  | NvRecord Memory Store Segment: Total Space                                                   |
| 632  | NvRecord Memory Store Segment: Free Space                                                    |
| 633  | NvRecord Memory Store Segment: Deleted Space                                                 |
| 1000 | BASIC compiler HASH value as a 32-bit decimal value                                           |
| 1001 | How RAND() generates values: 0 for PRNG and 1 for hardware assist                              |
| 1002 | Minimum baudrate                                                                             |
| 1003 | Maximum baudrate                                                                             |
| 1004 | Maximum STRING size                                                                         |

Exceptions

- Local Stack Frame Underflow
- Local Stack Frame Overflow

Arguments

`byVal varId AS INTEGER`

An integer ID which is used to determine which information is to be returned as described below.
## Table of Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1005     | 1: Run-time only implementation  
           3: Compiler included |
| 2000     | Reason for reset:  
           8: Self-reset due to Flash Erase  
           9: ATZ  
           10: Self-reset due to smart BASIC app invoking function RESET() |
| 2002     | Timer resolution in microseconds |
| 2003     | Number of timers available in a smart BASIC application |
| 2004     | Tick timer resolution in microseconds |
| 2005     | LMP version number for BT 4.0 spec |
| 2006     | LMP sub-version number |
| 2007     | Chipset company ID allocated by BT SIG |
| 2008     | Returns the current TX power setting (see also 2018) |
| 2009     | Number of devices in trusted device database |
| 2010     | Number of devices in trusted device database with IRK |
| 2011     | Number of devices in trusted device database with CSRK |
| 2012     | Max number of devices that can be stored in trusted device database |
| 2013     | Maximum length of a GATT Table attribute in this implementation |
| 2014     | Total number of transmission buffers for sending attribute NOTIFIES |
| 2015     | Number of transmission buffers for sending attribute NOTIFIES – free |
| 2016     | Radio activity of the baseband. A bit mask as follows:  
           Bit 0: Advertising  
           Bit 1: Connected as slave  
           Bit 2: Initiating  
           Bit 3: Scanning  
           Bit 4: Connected as master |
| 2018     | Returns the TX power while pairing in progress (see also 2008) |
| 2019     | Default ring buffer length for notify/indicates in GATT client manager (see BleGattcOpen function) |
| 2020     | Maximum ring buffer length for notify/indicates in GATT client manager (see BleGattcOpen function) |
| 2021     | Stack tide mark in percent. Values near 100 are not good |
| 2022     | Stack size |
| 2023     | Initial Heap size |
| 2040     | Max number of devices that can be stored in trusted device database |
| 2041     | Number of devices in trusted device database |
| 2042     | Number of devices in trusted device database classed as Rolling |
| 2043     | Number of devices in trusted device database that can Persist |
| 2100     | Connect Scan interval (in milliseconds) used when connecting |
| 2101 | Connect Scan window (in milliseconds) used when connecting |
| 2102 | Connect slave latency in outgoing connection request |
| 2105 | Multi-Link Connection Interval periodicity in milliseconds |
| 2150 | Scan Interval (in milliseconds) used when connecting |
| 2151 | Scan Window (in milliseconds) used when connecting |
| 2152 | Type of scanning: Active or Passive |

| 0x8000 to 0x81FF | Content of FICR register in the Nordic nrf51 chipset. In the nrf51 datasheet, in the FICR section, all the FICR registers are listed in a table with each register identified by an offset. For example, to read the Code memory page size which is at offset 0x010, call SYSINFO(0x8010) or in interactive mode use AT l 0x8010. |

**Interactive Command**: No

```plaintext
//Example :: SysInfo.sb (See in RM1xxCodeSnippets.zip)
PRINT "\nSysInfo 1000 = ";SYSINFO(1000) // BASIC compiler HASH value
PRINT "\nSysInfo 2003 = ";SYSINFO(2003) // Number of timers
PRINT "\nSysInfo 0x8010 = ";SYSINFO(0x8010) // Code memory page size from FICR
```

**Expected Output (For RM1xx):**

```
SysInfo 1000 = 1315489536
SysInfo 2003 = 8
SysInfo 0x8010 = 1024
```

SYSINFO is a core language function.

**SYSINFO$**

**FUNCTION**

Returns an informational string value depending on the value of `varId` argument.

**SYSSINFO$(varId)**

| Returns | STRING. Value of information corresponding to integer ID requested. |
| Exceptions |
| ▪ Local Stack Frame Underflow |
| ▪ Local Stack Frame Overflow |
| Arguments: |
| varId | `byVal` varId AS INTEGER |
|       | An integer ID which is used to determine which information is to be returned as described below. |
| 4     | The Bluetooth address of the module. It is seven bytes long. First byte is 00 for IEEE public address and 01 for random public address. Next six bytes are the address. |
A random public address unique to this module. May be the same value as in 4 above unless AT+MAC was used to set an IEEE MAC address. It is seven bytes long. First byte is 00 for IEEE public address and 01 for random public address. Next six bytes are the address.

Interactive Command

<table>

//Example :: SysInfo.sb (See in RM1xxCodeSnippets.zip)

```plaintext
PRINT "\nSysInfo$(4) = ";SYSINFO$(4) // address of module
PRINT "\nSysInfo$(14) = ";SYSINFO$(14) // public random address
PRINT "\nSysInfo$(0) = ";SYSINFO$(0)
```

Expected Output:

```
SysInfo$(4) = \01\FA\84\D7\D9\03
SysInfo$(14) = \01\FA\84\D7\D9\03
SysInfo$(0) =
```

SYSINFO$ is a core language function.

**UART (Universal Asynchronous Receive Transmit)**

**UartOpen**

**FUNCTION**

This function is used to open the main default UART peripheral using the parameters specified. See core manual for further details.

**UARTOPEN (baudrate,txbuflen,rxbuflen,stOptions)**

```plaintext
byVal stOptions AS STRING
This string (can be a constant) MUST be exactly 5 characters long where each character is used
to specify further comms parameters as follows.
Character Offset:

<table>
<thead>
<tr>
<th>stOptions</th>
<th>DTE/DCE role request:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>T – DTE</td>
</tr>
<tr>
<td></td>
<td>C – DCE</td>
</tr>
<tr>
<td>1</td>
<td>Parity:</td>
</tr>
<tr>
<td></td>
<td>N – None</td>
</tr>
<tr>
<td></td>
<td>O – Odd (Not Available)</td>
</tr>
<tr>
<td></td>
<td>E – Even (Not Available)</td>
</tr>
<tr>
<td>2</td>
<td>Databits: 8</td>
</tr>
<tr>
<td>3</td>
<td>Stopbits: 1</td>
</tr>
</tbody>
</table>
```
### Flow Control:

- **N** – None
- **H** – CTS/RTS hardware
- **X** – Xon/Xoff (Not Available)

### UartCloseEx

```plaintext
//Example :: UartCloseEx.sb (See in Firmware Zip file)
DIM rc1
DIM rc2

UartClose()
rc1 = UartOpen(9600,0,0,"CN81H")  //open as DTE at 300 baudrate, odd parity
    //8 databits, 1 stopbits, cts/rts flow control
PRINT "Laird"

IF UartCloseEx(1)! = 0 THEN
    PRINT "\nData in at least one buffer. Uart Port not closed"
ELSE
    rc1 = UartOpen(9600,0,0,"CN81H")  //open as DTE at 300 baudrate, odd parity
    PRINT "\nUart Port was closed"
ENDIF
```

**Expected Output:**

```
Laird
Data in at least one buffer. Uart Port not closed
```

UARTCLOSEEX is a core function.

### UartSetRTS

The RM1xx module does not offer the capability to control the RTS pin as the underlying hardware does not allow it. The function exists to enable porting of applications from platforms where an app has invoked it.

### UartBREAK

The RM1xx module does not offer the capability to send a BREAK signal.

If this feature is required, then the best way to expedite it is to put UART_TX and an I/O pin configured as an output through an AND gate.
For normal operation the general purpose output pin is set to logic high which means the output of the AND gate follows the state of the UART_TX pin.

When a BREAK is to be sent, the general purpose pin is set to logic high which means the output of the AND gate is low and remains low regardless of the state of the UART_TX pin.

I2C – Two Wire Interface (TWI)

The RM1xx can only be configured as an I2C master with the additional constraint that it be the only master on the bus and only 7-bit slave addressing is supported.

SPI Interface

The RM1xx module can only be configured as a SPI master.

4. CORE EXTENSIONS BUILT-IN ROUTINES

Miscellaneous Routines

AssertRM1xx

SUBROUTINE

This function’s main use case is during smartBASIC source compilation and the presence of at least one instance of this statement ensures that the smartBASIC application only fully compiles without errors on a RM1xx module. This ensures that apps for other modules are not mistakenly loaded into the RM1xx.

ASSERTRM1xx()

<table>
<thead>
<tr>
<th>Returns</th>
<th>Not Applicable as it is a subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>None</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

AssertRM1xx() //Ensure loading on RM1xx only

ASSERTRM1xx is an extension subroutine.

Input/Output Interface Routines

I/O and interface commands allow access to the physical interface pins and ports of the smartBASIC modules. Most of these commands are applicable to the range of modules. However, some are dependent on the actual I/O availability of each module.
### GPIO Events

#### EVGPIOCHANn
Here, n is from 0 to N where N is platform dependent and an event is generated when a preconfigured digital input transition occurs. The number of digital inputs that can auto-generate is hardware dependent. For the RM1xx module, N can be 0, 1, 2 or 3.

Use GpioBindEvent() to generate these events.

See example for GpioBindEvent()

#### EVDETECTCHANn
Here, n is from 0 to N where N is platform dependent and an event is generated when a preconfigured digital input transition occurs. The number of digital inputs that can auto-generate is hardware dependent. For the RM1xx module, N can only be 0.

Use GpioAssignEvent() to generate these events.

See example for GpioAssignEvent()

### GpioSetFunc

**FUNCTION**

This routine sets the function of the GPIO pin identified by the nSigNum argument.

The module datasheet contains a pinout table which denotes SIO (Special I/O) pins. The number designated for that special I/O pin corresponds to the nSigNum argument.

**GPIOSETFUNC** (nSigNum, nFunction, nSubFunc)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. The most typical value is 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>

</tbody>
</table>

**Note:** The internal reference voltage is 1.2V with +/- 1.5% accuracy.

**WARNING:** This subfunc value is ‘global’ and once changed will apply to all ADC inputs.

**Interactive Command:** NO
GPIOSETFUNC is a Module function.

**GpioConfigPwm**

**FUNCTION**

This routine configures the PWM (Pulse Width Modulation) of all output pins when they are set as a PWM output using GpioSetFunc() function described above.

**Note:** This is a ‘sticky’ configuration; calling it affects all currently configured PWM outputs. We recommend that this is called once at the beginning of your application and not changed again within the application unless all PWM outputs are deconfigured and then re-enabled after this function is called.

The PWM output is generated using 32-bit hardware timers. The timers are clocked by a 1 MHz clock source.

A PWM signal has a frequency and a duty cycle property; the frequency is set using this function and is defined by the nMaxResolution parameter. For a given nMaxResolution value, given that the timer is clocked using a 1 MHz source, the frequency of the generated signal is 1000000 divided by nMaxResolution. Hence if nMinFreqHz is more than the 1000000/nMaxResolution, this function will fail with a non-zero value.

The nMaxResolution can also be viewed as defining the resolution of the PWM output in the sense that the duty cycle can be varied from 0 to nMaxResolution. The duty cycle of the PWM signal is modified using the GpioWrite() command.

For example, a period of 1000 generates an output frequency of 1KHz, a period of 500, and a frequency of 2KHz etc.

On exit, the function returns with the actual frequency in the nMinFreqHz parameter.

**GPIOCFGPWM (nMinFreqHz, nMaxResolution)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Most typical value:</strong> 0x0000 (indicates a successful operation)</td>
<td></td>
</tr>

</table>

<table>
<thead>
<tr>
<th>Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>nMinFreqHz</strong></td>
</tr>
</tbody>
</table>
On entry this variable contains the minimum frequency desired for the PWM output. On exit, if successful, it contains the actual frequency of the PWM output.

<table>
<thead>
<tr>
<th><strong>nMaxResolution</strong></th>
<th>byVal nMaxResolution INTEGER.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This specifies the duty cycle resolution and the value to set to get a 100% duty cycle.</td>
</tr>
</tbody>
</table>

**Interactive Command**: No

// Example :: GpioConfigPWM() (See in Firmware Zip file)
DIM rc
DIM nFreqHz, nMaxRes

// we want a minimum frequency of 500Hz so that we can use a 100Hz low pass filter to
// create an analogue output which has a 100Hz bandwidth
nFreqHz = 500

// we want a resolution of 1:1000 in the generated analogue output
nMaxValUs = 1000

PRINT GpioConfigPWM(nFreqHz,nMaxRes)

PRINT "\nThe actual frequency of the PWM output is ";nFreqHz;"\n"

// now configure SIO2 pin as a PWM output
PRINT GpioSetFunc(2,2,2)    //3rd parameter is subfunc == PWM output

// Set PWM output to 0%
GpioWrite(2,0)

// Set PWM output to 50%
GpioWrite(2,(nMaxRes/2))

// Set PWM output to 100%
GpioWrite(2,nMaxRes)    // any value >= nMaxRes will give a 100% duty cycle

// Set PWM output to 33.333%
GpioWrite(2,(nMaxRes/3))

**Expected Output:**

0

The actual frequency of the PWM output is 1000

0

GPIOCONFIGPWM is a Module function.
GpioRead

FUNCTION

This routine reads the value from a SIO (special purpose I/O) pin.

The module datasheet contains a pinout table which mentions SIO (Special I/O) pins and the number designated for that special I/O pin corresponds to the nSigNum argument.

GPIOREAD (nSigNum)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, the value from the signal. If the signal number is invalid, it returns the value 0. For digital pins, the value is 0 or 1. For ADC pins it is a value in the range of 0 to M where M is the maximum based on the bit resolution of the analogue to digital converter.</th>
</tr>
</thead>
</table>
| Arguments | nSigNum byVal nSigNum INTEGER  
The signal number as stated in the pinout table of the module. |

//Example :: GpioRead.sb (See in Firmware Zip file)

```
DIM signal
signal = GpioRead(3)
PRINT signal
```

Expected Output:

1

GPIOREAD is a Module function.

GpioWrite

SUBROUTINE

This routine writes a new value to the GPIO pin. If the pin number is invalid, nothing happens.

If the GPIO pin has been configured as a PWM output, then the nNewValue specifies a value in the range 0 to N where N is the maximum PWM value that generates a 100% duty cycle output (a constant high signal) and N is a value that is configured using the function GpioConfigPWM().

If the GPIO pin has been configured as a FREQUENCY output, then the nNewValue specifies the desired frequency in Hertz in the range 0 to 4000000. Setting a value of 0 makes the output a constant low value. Setting a value greater than 4000000 clips the output to a 4 MHz signal.

GPIOWRITE (nSigNum, nNewValue)

| Arguments | nSigNum byVal nSigNum INTEGER.  
The signal number as stated in the pinout table of the module. |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
### nNewValue

<table>
<thead>
<tr>
<th>byVal nNewValue  INTEGER.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The value to be written to the port. If the pin is configured as digital, then 0 clears the pin and a non-zero value sets it.</td>
</tr>
<tr>
<td>If the pin is configured as analogue – value is written to the pin</td>
</tr>
<tr>
<td>If the pin is configured as a PWM – value sets the duty cycle</td>
</tr>
<tr>
<td>If the pin is configured as a FREQUENCY – value sets the frequency</td>
</tr>
</tbody>
</table>

### Interactive Command

<table>
<thead>
<tr>
<th>No</th>
</tr>
</thead>
</table>

```plaintext
//Example :: GpioWrite.sb (See in Firmware Zip file)

DIM rc,dutycycle,freqHz,minFreq

//set sio pin 1 to an output and initialise it to high
PRINT GpioSetFunc(1,2,0);"\n"

//set sio pin 5 to PWM output
minFreq = 500
PRINT GpioConfigPWM(minFreq,1024);"\n" //set max pwm value/resolution to 1:1024
PRINT GpioSetFunc(5,2,2);"\n"
PRINT GpioSetFunc(6,2,3);"\n\n" //set sio pin 6 to Frequency output

GpioWrite(18,0) //set pin 1 to low
GpioWrite(18,1) //set pin 1 to high

//Set the PWM output to 25%
GpioWrite(5,256) //256 = 1024/4

//Set the FREQ output to 4.236 Khz
GpioWrite(6,4236)

//Note you can generate a chirp output on sio 6 by starting a timer which expires
//every 100ms and then in the timer handler call GpioWrite(6,xx) and then
//increment xx by a certain value

Expected Output:

0000
```

GPIOWRITE is a Module function.

**GpioBindEvent**

**FUNCTION**

This routine binds an event to a level transition on a specified special I/O line configured as a digital input so that changes in the input line can invoke a handler in smart BASIC user code.
Note: In the RM1xx module, using this function results in over 1 mA of continuous current consumption from the power supply. If power is important, use GpioAssignEvent() instead which uses other resources to expedite an event.

**GPIOBINDEVENT (nEventNum, nSigNum, nPolarity)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Typical value: 0x0000 (indicates a successful operation)</th>

</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>
</tr>
</tbody>
</table>
| **nEventNum** | byVal nEventNum INTEGER  
The GPIO event number (in the range of 0 - N) which results in the event EVGPIOCHANn being thrown to the smart BASIC runtime engine. |
| **nSigNum** | byVal nSigNum INTEGER  
The signal number as stated in the pinout table of the module. |
| **nPolarity** | byVal nPolarity INTEGER  
States the transition as follows:  
0 Low to high transition  
1 High to low transition  
2 Either a low to high or high to low transition |
| Interactive Command | No |

//Example :: GpioBindEvent.sb (See in Firmware Zip file)

```sb
FUNCTION Btn0Press()
    PRINT "\nHello"
ENDFUNC 0

PRINT GpioBindEvent(0,16,1) //Bind event 0 to high low transition on sio16 (button0)
ONEVENT EVGPIOCHAN0 CALL Btn0Press //When event 0 happens, call Btn0Press

PRINT "\nPress button 0"
WAITEVENT
```

Expected Output:

```
0
Press button 0
Hello
```

GPIOBINDEVENT is a Module function.
GpioUnbindEvent

FUNCTION

This routine unbinds the runtime engine event from a level transition bound using GpioBindEvent().

GPIOUNBINDEVENT (nEventNum)

Returns
INTEGER, a result code.
Typical value: 0x0000 (indicates a successful operation)

Arguments

nEventNum
byVal nEventNum INTEGER.
The GPIO event number (in the range of 0 - N) which is disabled so that it no longer generates run-time events in smart BASIC.

Interactive Command
No

//Example :: GpioUnbindEvent.sb (See in Firmware Zip file)
FUNCTION Btn0Press()
    PRINT "\nHello"
ENDFUNC

FUNCTION Tmr0TimedOut()
    PRINT "\nNothing happened"
ENDFUNC

PRINT GpioBindEvent(0,16,1);"\n"

ONEVENT EVGPIOCHAN0 CALL Btn0Press
ONEVENT EVTMR0 CALL Tmr0TimedOut

PRINT GpioUnbindEvent(0);"\n"
PRINT "\nPress button 0\n"
TimerStart(0,8000,0)

WAITEVENT
Expected Output:

```
0
0

Press button 0
Nothing happened
```

GPIOUNBINDEVENT is a Module function.

**GpioAssignEvent**

**FUNCTION**

This routine assigns an event to a level transition on a specified special I/O line configured as a digital input. Changes in the input line can invoke a handler in *smart* BASIC user code.

**Note:** In the RM1xx, this function results in approximately 4 uA of continuous current consumption from the power supply. It is impossible to assign a polarity value which detects either level transitions.

0

Press button 0

Nothing happened

GPIOUNASSIGNEVENT is a Module function.

5. BLE EXTENSIONS BUILT-IN Routines

Bluetooth Low Energy (BLE) extensions are specific to the RM1xx smartBASIC BLE module and provide a high level managed interface to the underlying Bluetooth stack.

MAC Address

To address privacy concerns, there are four types of MAC addresses in a BLE device which can change as needed. For example, an iPhone regularly changes its BLE MAC address and it always exposes only its resolvable random address.

To manage this, the usual six octet MAC address is qualified on-air by a single bit which qualifies the MAC address as public or random. If public, then the format is as defined by the IEEE organization. If random, then it can be up to three types and this qualification is done using the upper two bits of the most significant byte of the random MAC address. The exact details and format of how the specification requires this to be managed is not relevant for the purpose of how BLE functionality as exposed in this module; only details on how various API functions in smartBASIC expect MAC addresses to be provided is described.

Where a MAC address is expected as a parameter (or provided as a response) it is always a STRING variable. This variable is seven octets long where the first octet is the address type and the other six octets are the usual MAC address in big endian format (so that most significant octet of the address is at offset 1), whether public or random.

The address type is:
0  Public
1  Random Static
2  Random Private Resolvable
3  Random Private Non-Resolvable

All other values are illegal

For example, to specify a public address which has the MAC potion as 112233445566 then the STRING variable contains seven octets 00112233445566 and a variable can be initialized using a constant string by escaping as follows:

<table>
<thead>
<tr>
<th>Static random address</th>
<th>01C12233445566 (upper tow bits of MAC portion == 11)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resolvable random address</td>
<td>02412233445566 (upper 2 bits of MAC portion == 01)</td>
</tr>
<tr>
<td>Non-resolvable address</td>
<td>03112233445566 (upper 2 bits of MAC portion == 00)</td>
</tr>
</tbody>
</table>

**Note:** The MAC address portion in smartBASIC is always in big endian format. If you sniff on-air packets, the same six packets appear in little endian format, hence reverse order; you will not see seven bytes, but a bit in the packet somewhere which specifies it to be public or random.

### Events and Messages

**EVBLE_CONN_TIMEOUT**

This event is thrown when a connection attempt initiated by the `BleConnect()` function times out.

```c
//See example for BleConnect()
```

**EVBLE_ADV_REPORT**

This event is thrown when an advert report is received whether successfully cached or not.

```c
//See example for BleScanGetAdvReport.sb
```

**EVBLE_FAST_PAGED**

This event is thrown when an advert report is received of type ADV_DIRECT_IND and the advert had a target address (InitA in the spec) which matches the address of this module.

```c
//See example for BleScanGetPagerAddr.sb
```

**EVBLE_SCAN_TIMEOUT**

This event is thrown when a scanning procedure initiated by the `BleScanStart()` function times out.
EVBLEMSG

BASIC application when a significant BLE-related event occurs. It does so by throwing this message (as opposed to an EVENT, which is akin to an interrupt and has no context or queue associated with it). The message contains two parameters: BASIC application when a significant BLE-related event has occurred. It does so by throwing this message (as opposed to an EVENT, which is akin to an interrupt and has no context or queue associated with it). The message contains two parameters:

- **msgID** – Identifies what event was triggered
- **msgCtx** – Conveys some context data associated with that event.

The smart BASIC application must register a handler function which takes two integer arguments to be able to receive and process this message.

Note: The messaging subsystem, unlike the event subsystem, has a queue associated with it and unless that queue is full, pends all messages until they are handled. Only messages that have handlers associated with them are inserted into the queue. This is to prevent messages that are not handled from filling that queue. The list of triggers and associated context parameter are described in Table 1.

**Table 1: Triggers and associated context parameters**

<table>
<thead>
<tr>

<tr>
<td>12</td>
<td>Heart Rate Client Characteristic Descriptor value has changed. (Notification enable state and msgCtx contains new value: 0 for disabled, 1 for enabled)</td>
</tr>
</tbody>
</table>
### MsgID | Description
--- | ---
14 | Connection parameters update and msgCtx is the conn handle.
15 | Connection parameters update fail and msgCtx is the conn handle.
16 | Connected to a bonded master and msgCtx is the conn handle.
17 | A new pairing has replaced old key for the connection handle specified.
18 | The connection is now encrypted and msgCtx is the conn handle.
19 | The supply voltage has dropped below that specified in the most recent call of SetPwrSupplyThreshMv() and msgCtx is the current voltage in millivolts.
20 | The connection is no longer encrypted and msgCtx is the conn handle.
21 | The device name characteristic in the GAP service of the local GATT table has been written by the remote GATT client.

**Note:** Message ID 13 is reserved for future use

The following is an example of how these messages can be used:

```vbnet
//Example :: EvBleMsg.sb (See in RM1xxCodeSnippets.zip)
DIM addr$ : addr$=
DIM rc

//==============================================================================
// This handler is called when there is a BLE message
//==============================================================================
FUNCTION HndlrBleMsg(BYVAL nMsgId AS INTEGER, BYVAL nCtx AS INTEGER)
    SELECT nMsgId
    CASE 0
        PRINT "\nBle Connection ";nCtx
        rc = BleAuthenticate(nCtx)
    CASE 1
        PRINT "\nDisconnected ";nCtx;"\n"
    CASE 18
        PRINT "\nConnection ";nCtx;" is now encrypted"
    CASE 16
        PRINT "\nConnected to a bonded master"
    CASE 17
        PRINT "\nA new pairing has replaced the old key"
    CASE ELSE
        PRINT "\nUnknown Ble Msg"
ENDSELECT
```
FUNCTION HndlrBlrAdvTimOut()
  PRINT "\nAdvertising stopped via timeout"
  PRINT "\nExiting..."
ENDFUNC

FUNCTION Btn0Press()
  PRINT "\nExiting..."
ENDFUNC

PRINT GpioSetFunc(16,1,0x12)
PRINT GpioBindEvent(0,16,0)

ONEVENT EVBLEMSG CALL HndlrBleMsg
ONEVENT EVBLE_ADV_TIMEOUT CALL HndlrBlrAdvTimOut
ONEVENT EVGPIOCHAN0 CALL Btn0Press

// start adverts
IF BleAdvertStart(0,addr$,100,10000,0)==0 THEN
  PRINT "\nAdvertisement started"
  PRINT "\nPress button 0 to exit\n"
ELSE
  PRINT "\nAdvertisement not successful"
ENDIF

WAITEVENT
Expected Output (When connection made with RM1xx):

Adverts Started
Press button 0 to exit

BLE Connection 3634
Connected to a bonded master
Connection 3634 is now encrypted
A new pairing has replaced the old key
Disconnected 3634
Exiting...

Expected Output (When no connection made):

Adverts Started
Press button 0 to exit

Advert stopped via timeout
Exiting...

**EVDISCON**

This event is thrown when there is a disconnection. It comes with two parameters:

- Parameter 1 – Connection handle
- Parameter 2 – The reason for the disconnection

For example: The reason can be 0x08 which signifies a link connection supervision timeout which is used in the Proximity Profile.

A full list of Bluetooth HCI result codes for the reason of disconnection can be determined and provided in this document [here](#).

```plaintext
//Example :: EvDiscon.sb (See in RM1xxCodeSnippets.zip)
DIM addr$ : addr$=""

FUNCTION HndlrBleMsg(BYVAL nMsgId AS INTEGER, BYVAL nCtx AS INTEGER)
    IF nMsgId==0 THEN
        PRINT "\nNew Connection ";nCtx
    ENDIF
```

// start adverts
IF BleAdvertStart(0,addr$,100,10000,0)==0 THEN
    PRINT "\nAdverts Started\n"
ELSE
    PRINT "\nAdvertisement not successful"
ENDIF

WAITEVENT

Expected Output:

Adverts Started
New Connection 2915
Connection 2915 Closed: 0x19

**EVCHARVAL**

This event is thrown when a characteristic has been written to by a remote GATT client. It comes with three parameters which are the characteristic handle that was returned when the characteristic was registered using the function `BleCharCommit()` the Offset and Length of the data from the characteristic value.

//Example :: EvCharVal.sb (See in RM1xxCodeSnippets.zip)

DIM hMyChar,rc,at$,conHndl
// Initialise and instantiate service, characteristic, start adverts
FUNCTION OnStartup()
    DIM rc, hSvc, attr$, adRpt$, addr$, scRpt$ : attr$="Hi"

    //commit service
    rc=BleSvcCommit(1,BleHandleUuid16(0x18EE),hSvc)
    //initialise char, write/read enabled, accept signed writes
    rc=BleCharNew(0x0A,BleHandleUuid16(1),BleAttrMetaData(1,1,20,0,rc),0,0)
    //commit char initialised above, with initial value "hi" to service 'hSvc'
    rc=BleCharCommit(hSvc,attr$,hMyChar)

    rc=BleScanRptInit(scRpt$)
    //Add 1 service handle to scan report
    //rc=BleAdvRptAddUuid16(scRpt$,0x18EE,-1,-1,-1,-1)
    //commit reports to GATT table - adRpt$ is empty
    rc=BleAdvRptsCommit(adRpt$,scRpt$)
    rc=BleAdvertStart(0,addr$,20,300000,0)
ENDFUNC rc

SUB CloseConnections()
    rc=BleDisconnect(conHndl)
    rc=BleAdvertStop()
ENDSUB

    PRINT "\nSend a new value to write to the characteristic\n"
ELSE
    PRINT "\nFailure OnStartup"
ENDIF

WAITEVENT

PRINT "\nExiting..."
Expected Output:

The characteristic’s value is HI
Write a new value to the characteristic

--- Connected to client
5 byte(s) have been written to char value attribute from offset 0
New Char Value: Hello

--- Disconnected from client
Exiting...

EVCHARHVC

This event is thrown when a value sent via an indication to a client gets acknowledged. It comes with one parameter – the characteristic handle that was returned when the characteristic was registered using the function BleCharCommit().

// Example :: EVCHARHVC charHandle

// See example that is provided for EVCHARCCCD

EVCHARCCCD

This event is thrown when the client writes to the CCCD descriptor of a characteristic. It comes with two parameters:

- The characteristic handle returned when the characteristic was registered with BleCharCommit()
- The new 16-bit value in the updated CCCD attribute.

//Example :: EvCharCccd.sb (See in RM1xxCodeSnippets.zip)

**EVCHARDESC**

This event is thrown when the client writes to writable descriptor of a characteristic which is not a CCCD or SCCD (CCCD and SCCD are catered for with their own dedicated messages). It comes with two parameters:

- The characteristic handle that was returned when the characteristic was registered using the function `BleCharCommit()`
- An index into an opaque array of handles managed inside the characteristic handle

Both parameters are supplied as-is as the first two parameters to the function `BleCharDescRead()`.

```vbnet
//Example :: EvCharDesc.sb (See in RM1xxCodeSnippets.zip)

DIM hMyChar, rc, at$, conHndl, hOtherDescr
//==============================================================================
// Initialise and instantiate service, characteristic, start adverts
//==============================================================================
Sub OnStartup()
  DIM rc, hSvc, at$, adRpt$, addr$, scRpt$, hOtherDscr, attr$, attr2$
  attr$="Hi"
  DIM charMet : charMet = BleAttrMetaData(1,1,20,0,rc)

  //Commit svc with handle 'hSvcUuid'
  rc=BleSvcCommit(1,BleHandleUuid16(0x18EE),hSvc)
  //initialise char, read/write enabled, accept signed writes
  rc=BleCharNew(0x4A,BleHandleUuid16(1),charMet,0,0)
  //Add another descriptor
  attr$="descr_value"
  rc=BleCharDescAdd(0x2999,attr$,BleAttrMetadata(1,1,20,0,rc))
```
//commit char initialised above, with initial value "hi" to service 'hMyChar'
attr2$="char value"
rc=BleCharCommit(hSvc,attr2$,hMyChar)
rc=BleAdvRptInit(adRpt$,0x02,0,20)
rc=BleScanRptInit(scRpt$)

//get UUID handle for other descriptor
hOtherDscr=BleHandleUuid16(0x2905)

//Add 'hSvc','hMyChar' and the other descriptor to the advert report
rc=BleAdvRptAddUuid16(adRpt$,0x18EE,0x2905,-1,-1,-1,-1)
rc=BleAdvRptAddUuid16(scRpt$,0x2905,-1,-1,-1,-1)

//commit reports to GATT table - adRpt$ is empty
rc=BleAdvRptsCommit(adRpt$,scRpt$)
rc=BleAdvertStart(0,addr$,20,300000,0)
rc=GpioBindEvent(1,16,1)  //Channel 1, bind to low transition on GPIO pin 16
ENDSUB

//==============================================================================
// Close connections so that we can run another app without problems
//==============================================================================
SUB CloseConnections()
    rc=BleDisconnect(conHndl)
    rc=BleAdvertStop()
    rc=GpioUnbindEvent(1)

"

EVNOTIFYBUF

When in a connection and attribute data is sent to the GATT client using a notify procedure (such as the function BleCharValueNotify()) or when a Write_with_no_response is sent by the GATT client to a remote server, they are stored in temporary buffers in the underlying stack. There is finite number of these
temporary buffers and if they are exhausted, the notify function or the write_with_no_resp command will fail with a result code of 0x6803 (BLE_NO_TX_BUFFERS). Once the attribute data is transmitted over the air, given there are no acknowledges for Notify messages, the buffer is freed to be reused.

This event is thrown when at least one buffer has been freed; the smartBASIC application can then handle this event to retrigger the data pump for sending data using notifies or writes_with_no_resp commands.

**Note:** When sending data using Indications, this event is not thrown because those messages have to be confirmed by the client which results in a EVCHARHVC message to the smartBASIC application. Likewise, writes which are acknowledged also do not consume these buffers.

```basic
//Example :: EvNotifyBuf.sb (See in RM1xxCodeSnippets.zip)

DIM hMyChar,rc,at$,conHndl,ntfyEnabled

//==============================================================================
// Initialise and instantiate service, characteristic, start adverts
//==============================================================================
FUNCTION OnStartup()
    DIM rc, hSvc, at$, attr$, adRpt$, addr$, scRpt$

Miscellaneous Functions

This section describes all BLE-related functions that are not related to advertising, connection, security manager, or GATT.

**BleTxPowerSet**

**FUNCTION**

This function sets the power of all packets that are transmitted subsequently.

The actual value is determined by scanning through the value list (4, 0, -4, -8, -12, -16, -20, -30, -55) so that the highest value in the list which is less than the desired value is set. Note that if desired value is less than -55 then -55 is selected.

For example, setting 1000 results in +4; -3 results in -4; -100 results in -55.

At any time SYSINFO(2008) returns the actual transmit power setting. Or, when in command mode, use the command AT I 2008.

**BLETXPOWERSET**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Typical value</strong>:</td>
<td>0x0000 (indicates a successful operation)</td>
</tr>
<tr>
<td><strong>Arguments</strong></td>
<td></td>
</tr>
<tr>
<td>nTxPower</td>
<td>ByVal nTxPower AS INTEGER.</td>
</tr>
<tr>
<td>Specifies the new transmit power in dBm units to be used for all subsequent Tx packets.</td>
<td></td>
</tr>
<tr>
<td>The actual value is determined by scanning through the value list (4, 0, -4, -8, -12, -16, -20, -30, -55) so that the highest value in the list which is less than the desired value is set. Note that if desired value is less than -55 then -55 is selected.</td>
<td></td>
</tr>
</tbody>
</table>

**Interactive Command**: No
Expected Output:

```
rc = 0
Tx power : desired= 1000    actual= 4
Tx power : desired= 8       actual= 4
Tx power : desired= 2       actual= 0
Tx power : desired= -10     actual= -12
Tx power : desired= -25     actual= -30
Tx power : desired= -45     actual= -55
Tx power : desired= -1000   actual= -55
```

BLETXPOWERSET is an extension function.

**BleTxPwrWhilePairing**

**FUNCTION**

This function sets the transmit power of all packets that are transmitted while a pairing is in progress. This mode of pairing is referred to as Whisper Mode Pairing. The actual value is clipped to the transmit power for normal operation which is set using BleTxPowerSet() function.
The actual value is determined by scanning through the value list (4, 0, -4, -8, -12, -16, -20, -30, -55) so that the highest value in the list which is less than the desired value is set. Note that if desired value is less than -55, then -55 is selected.

For example, setting 1000 results in +4; -3 results in -4; -100 results in -55.

At any time SYSINFO(208) returns the actual transmit power setting. Or, when in command mode, use the command AT I 208.

```python
BleConfigDcDc(2) //Set for automatic operation
```

BLECONFIGDCDC is an extension function.

**Advertising Functions**

**Note:** The RM1xx module is NOT capable of being a peripheral device and so, although the functions described below exist, most return an error. They only function as described in the RM1xx module, or in the future in a module with a combined central and peripheral stack.
An advertisement consists of a packet of information with a header identifying it as one of four types along with an optional payload that consists of multiple advertising records, referred to as AD in the rest of this manual.

Each AD record consists of up to three fields:

- **First field** – One octet in length and contains the number of octets that follow it that belong to that record
- **Second field** – One octet and is a tag value which identifies the type of payload that starts at the next octet. Hence the payload data is \( \text{length} - 1 \).

A special NULL AD record consists of only one field – the length field when it contains just the 00 value.

The specification also allows custom AD records to be created using the Manufacturer Specific Data AD record.

Refer to the *Supplement to the Bluetooth Core Specification, Version 1, Part A* which has the latest list of all AD records. You must register as at least an Adopter, which is free, to gain access to this information. It is available at [https://www.bluetooth.org/docman/handlers/downloaddoc.ashx?doc_id=245130](https://www.bluetooth.org/docman/handlers/downloaddoc.ashx?doc_id=245130)

**BleAdvertStart**

**FUNCTION**

This function causes a BLE advertisement event as per the Bluetooth Specification. An advertisement event consists of an advertising packet in each of the three advertising channels.

The type of advertisement packet is determined by the nAdvType argument and the data in the packet is initialized, created, and submitted by the BLEADVRPTINIT, BLEADVRPTADDxxx, and BLEADVRPTCOMMIT functions respectively.

If the Advert packet type (nAdvType) is specified as 1 (ADV_DIRECT_HIGH_DUTY_CYCLE) then the peerAddr$ string must not be empty and should be a valid address. When advertising with this packet type, the timeout is automatically set to 1280 milliseconds.

If the Advert packet type (nAdvType) is specified as 4 (ADV_DIRECT_LOW_DUTY_CYCLE) then the peerAddr$ string must not be empty and should be a valid address. When advertising with this packet type, the timeout is as per the interval and timeout values specified.

When filter policy is enabled, the whitelist consisting of all bonded masters is submitted to the underlying stack so that only those bonded masters result in scan and connection requests being serviced.

**Note:** nAdvTimeout is rounded up to the nearest 1000 msec.

**BLEADVERTSTART (nAdvType, peerAddr$, nAdvInterval, nAdvTimeout, nFilterPolicy)**

| **Returns** | INTEGER, a result code. |
| **Typical value:** | 0x0000 (indicates a successful operation) |
| If a 0x6A01 resultcode is received, it implies whitelist has been enabled but the Flags AD in the advertising report is set for limited and/or general discoverability. The solution is to resubmit a new advert report which is made up so that the nFlags argument to BleAdvRptInit() function is 0. |
The BT 4.0 spec disallows discoverability when a whitelist is enabled during advertisement see Volume 3, Sections 9.2.3.2 and 9.2.4.2.

<table>
<thead>

<th>Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nAdvType</td>
<td>byVal nAdvType AS INTEGER. Specifies the advertisement type as follows:</td>
</tr>
<tr>
<td></td>
<td>0 ADV_IND – Invites connection requests</td>
</tr>
<tr>
<td></td>
<td>1 ADV_DIRECT_HIGH_DUTY_CYCLE – Invites connection from addressed device using high duty cycle timing. nAdvInternal and nAdvTimeout are ignored and interval is set to 3.75ms and Timeout to 1.28 seconds as per the specification. See ADV_DIRECT_LOW_DUTY_CYCLE for an alternative.</td>
</tr>
<tr>
<td></td>
<td>2 ADV_SCAN – Invites scan requests for more advert data</td>
</tr>
<tr>
<td></td>
<td>3 ADV_NONCONN – Does not accept connections and/or active scans</td>
</tr>
<tr>
<td></td>
<td>4 ADV_DIRECT_LOW_DUTY_CYCLE – Invites connection from addressed device using low duty cycle timing using nAdvInternal and nAdvTimeout specified</td>
</tr>
<tr>
<td>peerAddr$</td>
<td>byRef peerAddr$ AS STRING. It can be an empty string that is omitted if the advertisement type is not ADV_DIRECT_IND. This is only required when nAdvType == 1. When not empty, a valid address string is exactly seven octets long (such as 00\11\22\33\44\55\66), where the first octet is the address type and the rest of the 6 octets is the usual MAC address in big endian format (so that most significant octet of the address is at offset 1), whether public or random.</td>
</tr>
<tr>
<td></td>
<td>0 Public</td>
</tr>
<tr>
<td></td>
<td>1 Random Static</td>
</tr>
<tr>
<td></td>
<td>2 Random Private Resolvable</td>
</tr>
<tr>
<td></td>
<td>3 Random Private Non-resolvable</td>
</tr>
<tr>
<td></td>
<td>All other values are illegal.</td>
</tr>
<tr>
<td>nAdvInterval</td>
<td>byVal nAdvInterval AS INTEGER. The interval between two advertisement events (in milliseconds). An advertisement event consists of a total of three packets being transmitted in the three advertising channels. Interval range: Between 20 and 10240 milliseconds.</td>
</tr>
<tr>
<td>nAdvTimeout</td>
<td>byVal nAdvTimeout AS INTEGER. The time after which the module stops advertising (in milliseconds). Value range: Between 0 and 16383000 milliseconds (rounded up to the nearest one seconds or 1000 milliseconds). A value of 0 means disable the timeout, but note that if limited advert modes was specified in BleAdvRptInit() then the timeout is capped to 180000 milliseconds as per the Bluetooth Specification. When the advert type specified is ADV_DIRECT_IND, the timeout is automatically set to 1280 milliseconds as per the Bluetooth Specification. Warning: To save power, do not set this to (e.g.) 100 milliseconds.</td>
</tr>
</tbody>
</table>
**nFilterPolicy**

byVal nFilterPolicy AS INTEGER.

Specifies the filter policy for the whitelist consisting of all bonded masters as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable whitelist</td>
</tr>
<tr>
<td>1</td>
<td>Filter scan request; allow connection request from any</td>
</tr>
<tr>
<td>2</td>
<td>Filter connection request; allow scan request from any</td>
</tr>
<tr>
<td>3</td>
<td>Filter scan request and connection request</td>
</tr>
</tbody>
</table>

If the filter policy is not 0, the whitelist is enabled and filled with all the addresses of all the devices in the trusted device database.

If you search for bluetooth devices on your device, you should see 'Laird RM1xx'

Advert stopped via timeout
Exiting...
BLEADVERTSTOP is an extension function.

**BleAdvRptInit**

**FUNCTION**

**Note:** The function is not available in the RM1xx module and always returns an error.

This function is used to create and initialize an advert report with a minimal set of ADs (advertising records) and store it the string specified. It is not advertised until BLEADVRPTSCOMMIT is called.

This report is for use with advertisement packets.
BLEADVRPTINIT, nFlagsAD, nAdvAppearance, nMaxDevName)

Returns
INTEGER, a result code. The most typical value is 0x0000, indicating a successful operation.

Arguments
advRpt$ byRef advRpt$ AS STRING. This contains an advertisement report.

nFlagsAD byVal nFlagsAD AS INTEGER. Specifies the flags AD bits where bit 0 is set for limited discoverability and bit 1 is set for general discoverability. Bit 2 is forced to 1 and bits 3 and 4 are forced to 0. Bits 3 to 7 are reserved for future use by the BT SIG and must be set to 0.

Note: If a whitelist is enabled in the BleAdvertStart() function then both Limited and General Discoverability flags MUST be 0 as per the BT 4.0 specification (Volume 3, Sections 9.2.3.2 and 9.2.4.2)

nAdvAppearance byVal nAdvAppearance AS INTEGER. Determines whether the appearance advert should be added or omitted as follows:

0 Omit appearance advert
1 Add appearance advert as specified in the GAP service which is supplied via the BleGapSvcInit() function.

nMaxDevName byVal nMaxDevName AS INTEGER. The n leftmost characters of the device name specified in the GAP service. If this value is set to 0 then the device name is not included.

Interactive Command No

//Example :: BleAdvRptInit.sb (See in RM1xxCodeSnippets.zip)
DIM advRpt$ : advRpt$=""
DIM discovMode : discovMode=0
DIM advAppearance : advAppearance = 1

DIM advApprnce : advApprnce = 1
DIM maxDevName : maxDevName = 10

PRINT BleAdvRptInit(advRpt$, discovMode, advApprnce, maxDevName)
PRINT BleAdvRptAddUuid16(advRpt$, 0x180F,0x180A, -1, -1, -1, -1)
PRINT BleAdvRptsCommit(advRpt$, scRpt$)

// Only the advert report will be updated.
```
Expected Output:

BLEADVRPTSCOMMIT is an extension function.

**Scanning Functions**

When a peripheral advertises, the advert packet consists type of advert, address, RSSI, and some user data information.

A central role device enters scanning mode to receive these advert packets from any device that is advertising.

For each advert that is received the data is cached in a ring buffer, if space exists and the EVBLE_ADV_REPORT event is thrown to the smartBASIC application so that it can invoke the function BleScanGetAdvReport() to read it.

The scan procedure ends when it times out (timeout parameter is supplied when scanning is initiated) or is explicitly instructed to abort or stop.

**Note:** While scanning for a long period of time, it is possible that a peripheral device is advertising for a connection to it using the ADV_DIRECT_IND advert type. When this happens, it is good practice for the central device to stop scanning and initiate the connection. To cater for this specific scenario, which would normally require the central device to look out for that advert type and the self-address, the EVBLE_FAST_PAGED event is thrown to the application. The user app must install a handler for that event which stops the scan procedure and immediately start a connection procedure.

For more information about adverts see the section “Advertising Functions”

**BleScanStart**

**FUNCTION**

This function is used to start a scan for adverts which may result in at least one of these events being thrown:

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVBLE_SCAN_TIMEOUT</td>
<td>End of scanning</td>
</tr>
<tr>
<td>EVBLE_ADV_REPORT</td>
<td>Advert report received</td>
</tr>
<tr>
<td>EVBLE_FAST_PAGED</td>
<td>Peripheral inviting connection to this module</td>
</tr>
</tbody>
</table>

The event EVBLE_ADV_REPORT is received when an advert has been successfully cached in a ring buffer. The handler should call the function BleScanGetAdvReport() repeatedly to read all the advert reports that have been cached until the cache is empty, otherwise there is a risk that advert reports will be discarded. The output parameter nDiscarded returns the number of discarded reports, if any.
The event EVBLE_FAST_PAGED is received when a peripheral has sent an advert with the address of this module. The handler should stop scanning using BleScanStop() and then initiate a connection using BleConnect().

There are three parameters used when initiating a scan that are configurable using BleScanConfig(), otherwise default values are used:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Interval</td>
<td>Specify the duty cycle for listening for adverts.</td>
</tr>
<tr>
<td></td>
<td>Default values:</td>
</tr>
<tr>
<td>Scan Window</td>
<td>Specify the duration of listening for adverts.</td>
</tr>
<tr>
<td></td>
<td>Default values:</td>
</tr>
<tr>
<td>Scan Type</td>
<td>Default: Active</td>
</tr>
</tbody>
</table>

Active scanning means that for each advert received, if it is of type ADV_IND or ADV_DISCOVER_IND then a SCAN_REQ is sent to the advertising device so that the data in the scan response can be appended to the data that has already been received for the advert.

These values for these default parameters can be changed prior to invoking this function by calling the function BleScanConfig() appropriately.

There can be situations where there are many peripherals advertising and it may desirable to save power by not having to process all the adverts that are received. For this situation, this function takes a filter parameter which enables an opaque object to be presented to the baseband which contains a whitelist of MAC addresses. This means that only addresses that match those in the object get transferred to upper layers for further processing. This opaque object consisting of whitelisted mac addresses is created and modified using the functions BleWhiteListCreate(), BleWhiteListAddAddr(), and BleWhiteListAddIrk().

Note: IRK stands for Identity Resolving Key.

Finally, be aware that scanning is a memory-intensive operation and so heap memory is used to manage a cache. If the heap is fragmented, it is likely this function will fail with an appropriate resultcode returned. When that happens, you can call reset() and then attempt the scan start again. The memory that is allocated to manage this scan process is NOT released when the scanning times out. To force release of that memory, it is recommend starting the scan and then immediately calling BleScanStop().

BLESCANSTART, nFilterHandle))

Returns

INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation.

Arguments

scanTimeoutMs byVAL scanTimeoutMs AS INTEGER.
The length milliseconds the scan for adverts lasts.
If it times out, then the event EVBLE_SCAN_TIMEOUT is thrown to the smartBASIC application.
Valid range – 0 to 65535000 milliseconds (about 18 hours).
If 0 is supplied, it will not start a timer and scanning can only be stopped by calling either BleScanAbort() or Ble ScanStop().
nFilterHandle

byVAL nFilterHandle AS INTEGER
This must be 0 to specify no filtering of adverts, otherwise it will be a value returned by BleWhiteListCreate() and subsequently updated by BleWhiteListAddAddr() and/or BleWhiteListAddIrk(). When non-zero, only devices with matching address (or resolvable address corresponding to the IRK) result in a EVBLE_ADV_REPORT event to the smartBASIC application.

Interactive Command
No

//Example :: BleScanStart.sb (See in RM1xxCodeSnippets.zip)
DIM rc

'//Scan for 20 seconds with no filtering
rc = BleScanStart(20000, 0)

IF rc==0 THEN
   PRINT "\nScanning"
ELSE
   PRINT "\nError: "; INTEGER.H'rc
ENDIF

'//This handler will be called when scanning times out
FUNCTION HndlrScanTO()
   PRINT "\nScan timeout"
ENDFUNC 0

ONEVENT EVBLE_SCAN_TIMEOUT CALL HndlrScanTO

WAIT EVENT

Expected Output:
Scanning
Scan timeout

BLESCANSTART is an extension function.
**BleScanAbort**

**FUNCTION**

This function is used to cancel an ongoing scan for adverts which has not timed out. It takes no parameters since there can only be one scan in progress.

Use the value returned by SYSINFO(2016) to determine if there is an ongoing scan operation in progress. The value is a bit mask:

<table>
<thead>
<tr>
<th>Bit 0</th>
<th>Set if advertising is in progress (not possible with the RM1xx)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 1</td>
<td>Set if there is already a connection in the peripheral role (not possible with the RM1xx)</td>
</tr>
<tr>
<td>Bit 2</td>
<td>Set if there is a current connection attempt ongoing</td>
</tr>
<tr>
<td>Bit 3</td>
<td>Set when scanning</td>
</tr>
<tr>
<td>Bit 4</td>
<td>Set if there is already a connection to a peripheral</td>
</tr>
</tbody>
</table>

**Note:** There is also BleScanStop() which also cancels an ongoing scan. The difference is that, by calling BleScanAbort(), the memory that was allocated from the heap by BleScanStart() is not released back to the heap. The scan manager retains it for the next scan operation.

**BLESCANABORT()**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>None</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

```plaintext
//Example :: BleScanAbort.sb (See in RM1xxCodeSnippets.zip)
DIM rc, startTick

'//Scan for 20 seconds with no filtering
rc = BleScanStart(20000, 0)

IF rc==0 THEN
   PRINT "\nScanning"
ELSE
   PRINT "\nError: "; INTEGER.H'rc
ENDIF

'//Wait 2 seconds before aborting scan
startTick = GetTickCount()
WHILE GetTickSince(startTick) < 2000
ENDWHILE

'//If scan in progress, abort
```
Expected Output:

```
Scanning
Aborting scan
Scan aborted
```

BLESCANABORT is an extension function.

**BleScanStop**

**FUNCTION**

This function is used to cancel an ongoing scan for adverts which has not timed out. It takes no parameters since there can only be one scan in progress.

Use the value returned by SYSINFO(2016) to determine if there is an ongoing scan operation in progress. The value is a bit mask:

- **Bit 0**: Set if advertising is in progress (not possible with the RM1xx)
- **Bit 1**: Set if there is already a connection in the peripheral role (not possible with the RM1xx)
- **Bit 2**: Set if there is a current connection attempt ongoing
- **Bit 3**: Set when scanning
- **Bit 4**: Set if there is already a connection to a peripheral

**Note:** There is also BleScanAbort() which also cancels an ongoing scan. The difference is that, by calling BleScanStop(), the memory that was allocated from the heap by BleScanStart() is released back to the heap. The scan manager must reallocate the memory if BleScanStart() is called again.

**BLESCANSTOP()**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>None</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

//Example :: BleScanStop.sb (See in RM1xxCodeSnippets.zip)
DIM rc, startTick

'//Scan for 20 seconds with no filtering
rc = BleScanStart(20000, 0)

IF rc==0 THEN
    PRINT "\nScanning"
ELSE
    PRINT "\nError: "; INTEGER.H'rc
ENDIF

'//Wait 2 seconds before aborting scan
startTick = GetTickCount()
WHILE GetTickCount(startTick) < 2000
ENDWHILE

'//If scan in progress, abort
IF SysInfo(2016) == 0x08 THEN
    PRINT "\nStop scanning. Freeing up allocated memory"
    rc = BleScanStop()
    IF SysInfo(2016) == 0 THEN
        PRINT "\nScan stopped"
    ENDIF
ENDIF

Expected Output:

Scanning
Stop scanning. Freeing up allocated memory
Scan stopped

BLESCANSTOP is an extension function.

BleScanFlush

FUNCTION

This function is used to flush the buffer that contains advert reports that are currently in the internal cache waiting to be read by the function BleScanGetAdvReport().

When scanning is initiated using BleScanStart() the internal cache is automatically flushed so no need to call this function prior to starting a scan.
BLESCANFLUSH()

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>None</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

```plaintext
DIM rc

'//Flush the advert report cache
rc = BleScanFlush()
```

BLESCANFLUSH is an extension function.

**BleScanConfig**

**FUNCTION**

This function is used to modify the default parameters that are used when initiating a scan operation using BleScanStart().

The following lists the default parameters and their settings:

<table>
<thead>
<tr>
<th>Scan Interval</th>
<th>80 milliseconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Window</td>
<td>40 milliseconds</td>
</tr>
<tr>
<td>Scan Type (Active/Passive)</td>
<td>Active</td>
</tr>
<tr>
<td>Minimum Reports in the Cache</td>
<td>4</td>
</tr>
</tbody>
</table>

**Note:** The default Scan Window and Interval give a 50% duty cycle. The 50% duty cycle attempts to ensure that connection events for existing connections are missed as infrequently as possible.

**BLESCANCONFIG**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>configID byVal configID AS INTEGER This identifies the value to update as follows: 0 Scan Interval in milliseconds (range 0..10240) 1 Scan Window in milliseconds (range 0..10240) 2 Scan Type (0=Passive, 1=Active) 3 Advert Report Cache Size For all other configID values, the function returns an error. configValue byVal configValue AS INTEGER This contains the new value to set in the parameters identified by configID.</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>
//Example :: BleScanConfig.sb (See in RM1xxCodeSnippets.zip)
DIM rc, startTick

PRINT "\nScan Interval: "; SysInfo(2150)  //get current scan interval
PRINT "\nScan Window: "; SysInfo(2151)  //get current scan window
PRINT "\nScan Type: ";
IF SysInfo(2152)==0 THEN  //get current scan type
    PRINT "Passive"
ELSE
    PRINT "Active"
ENDIF
PRINT "\nReport Cache Size: "; SysInfo(2153)  //get report cache size

PRINT "\nSetting new parameters..."
r = BleScanConfig(0, 100)       //set scan interval to 100
rc = BleScanConfig(1, 50)       //set scan window to 50
rc = BleScanConfig(2, 0)        //set scan type to passive
rc = BleScanConfig(3, 3)        //set report cache size

PRINT "\n--- New Parameters:"
PRINT "\nScan Interval: "; SysInfo(2150)  //get current scan interval
PRINT "\nScan Window: "; SysInfo(2151)  //get current scan window
PRINT "\nScan Type: ";
IF SysInfo(2152)==0 THEN  //get current scan type
    PRINT "Passive"
ELSE
    PRINT "Active"
ENDIF
PRINT "\nReport Cache Size: "; SysInfo(2153)  //get report cache size
BLESCANCONFIG is an extension function.

**BleScanGetAdvReport**

**FUNCTION**

When a scan is in progress after having called BleScanStart() for each advert report the information is cached in a queue buffer and a EVBLE_ADV_REPORT event is thrown to the smartBASIC application.

This function is used by the smartBASIC application to extract it from the queue for further processing in the handler for the EVBLE_ADV_REPORT event.

The information that is retrieved consists of the address of the peripheral that sent the advert, the data payload, the number of adverts (all, not just from that peripheral) that have been discarded since the last time this function was called and the RSSI value for that packet. The RSSI can be used to determine the closest device, but please be aware that due to fading and reflections it is possible that a device further away could result in a higher RSSI value.

**BLESCANGETADVREPORT$, advData$, nDiscarded, nRssi)\)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>periphAddr$ byREF periphAddr$ AS STRING On return this parameter is updated with the address of the peripheral that sent the advert.</td>
</tr>
<tr>
<td></td>
<td>advData$ byREF advData$ AS STRING On return this parameter is updated with the data payload of the advert which consists of multiple AD elements.</td>
</tr>
</tbody>
</table>
**nDiscarded**

byREF nDiscarded AS INTEGER

On return this parameter is updated with the number of adverts that were discarded because there was no space in the internal queue.

**nRssi**

byREF nRssi AS INTEGER

On return this parameter is updated with the RSSI as reported by the stack for that advert.

**Note:** This is NOT a value that is sent by the peripheral but a value that is calculated by the receiver in this module.

**Interactive Command**

No

**Note:** This code snippet was tested with another RM1xx running the iBeacon app (see in smartBASIC_Sample_Apps folder) on Peripheral firmware.

```plaintext
//Example :: BleScanGetAdvReport.sb (See in RM1xxCodeSnippets.zip)
DIM rc

'//Scan for 5 seconds with no filtering
rc = BleScanStart(5000, 0)

IF rc==0 THEN
   PRINT "\nScanning"

BLESCANGETADVREPORT is an extension function.

BleGetADbyIndex

FUNCTION

This function is used to extract a copy of the nth (zero based) advertising data (AD) element from a string which is assumed to contain the data portion of an advert report, incoming or outgoing.

Note: If the last AD element is malformed then it is treated as not existing. For example, it is malformed if the length byte for that AD element suggests that more data bytes are required than actually exist in the report string.
### BLEGETADBYINDEX, rptData$, nADtag, ADval$)

Error reading AD: 00006060

BLEGETADBYINDEX is an extension function.

BleGetADbyTag

FUNCTION
This function is used to extract a copy of the first advertising data (AD) element that has the tag byte specified from a string which is assumed to contain the data portion of an advert report, incoming or outgoing. If multiple instances of that AD tag type are suspected, then use the function BleGetADbyIndex to extract.

Note: If the last AD element is malformed then it is treated as not existing. For example, it is malformed if the length byte for that AD element suggests that more data bytes are required than actually exist in the report string.

BLEGETADBYTAG$, nADtag, ADval$)

Returns INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation.
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rptData$</td>
<td>byREF rptData$ AS STRING. This parameter is a string that contains concatenated AD elements which are either constructed for an outgoing advert or received in a scan (depends on module variant)</td>
</tr>
<tr>
<td>nADTag</td>
<td>byVAL nADTag AS INTEGER. This parameter specifies the single byte tag value for the AD element that is to returned in the ADval$ parameter. Only the first instance can be catered for. If multiple instances are suspected, then use BleAdvADbyIndex() to extract it.</td>
</tr>
<tr>
<td>ADval$</td>
<td>byREF ADval$ AS STRING. When the nth index is found, the data excluding single byte the tag value for that AT element is returned in this parameter.</td>
</tr>
</tbody>
</table>

Interactive Command

AD element with tag 0x000000EE is AABBCCDDEEFF
Error reading AD: 00006060

BLEGETADBYTAG is an extension function.

BleScanGetPagerAddr

FUNCTION

When a scan is in progress after calling BleScanStart(), an EVBLE_FAST_PAGED event is thrown whenever an ADV_DIRECT_IND advert is received with the address of this module, requesting a connection to it.

This function returns the address of the peripheral requesting a connection and the RSSI. It should be used in the handler of the EVBLE_FAST_PAGED event to get the peripheral’s address. Scanning should then be stopped using either BleScanAbort() or BleScanStop(). You can then use the address supplied by this function to connect to the peripheral using BleConnect() if that is the desired use case. The Bluetooth specification does NOT mandate a connection.

BLESCANGETPAGERADDR$, nRssi)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>

Advert received from peripheral 01D8CFCF14498D with RSSI -96
requesting a connection to this module

BLESCANGETPAGERADDR is an extension function.
Whitelist Management Functions

**IMPORTANT!** The functions in this section are still in alpha state and should not be used.

The BLE paradigm is to consume as little power as possible so that operation from whatever power source lasts as long as possible.

One way to minimize power consumption is to ensure that incoming radio packets are filtered at the baseband level so that only a subset of addresses result in upper layers being informed about those radio packets.

This subset list of addresses is referred to as a whitelist in the Bluetooth specification. When a device powers up, the whitelist is empty. It is up to the upper layers to populate that list.

This section deals with all smartBASIC functions that enable that whitelist to be created in an opaque object for other operations such as BleScanStart() to use and activate. The functions allow creation, addition of addresses and identity resolving keys (IRKs), and destruction of the whitelist.

An identity resolving key (IRK) is a 128-bit value that is used as a key in an AES encryption EBC algorithm along with a three-byte random number to create another three-byte value such that when they are concatenated a resolvable MAC address is created as per the Bluetooth specification. The upper two bits of this six-byte MAC address is adjusted to signify that it is a resolvable random MAC address.

The receiving device examines the upper two bits and if it signifies a resolvable address, then it takes the relevant three bytes from that address and uses an IRK that it acquired from a device through a bonding process to determine whether it is a known address. For whitelisting purposes, all of this is done by the lower layers in the baseband.

**BleWhiteListCreate**

**FUNCTION**

This function is used to create a whitelist which is empty but contains enough memory to hold a maximum number of MAC addresses and a maximum number of Identity Resolving Keys (IRKs).

It returns a handle to the opaque object which is then subsequently used with the other whitelisted API functions.

**Note:** Do NOT destroy this object using BleWhiteListDestroy() while the object is in use by the underlying stack. This results in unpredictable behaviour.

**BleWhiteListCreate(maxMacAddr, maxIRKs)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a handle that identifies the opaque object that was created.</td>
<td></td>
</tr>
<tr>
<td>It is 0 if there was no free memory in the heap to create it. Always check for this.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
<th>byVAL maxMacAddr AS INTEGER.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The is the maximum number of addresses that are stored in the created whitelist opaque object. Each MAC address is a seven-byte entity: six for the address and the seventh for the type.</td>
<td></td>
</tr>
</tbody>
</table>
To add a key to this list, use the BleWhiteListAddAddr() function.

### maxIRKs
byVAL maxIRKs AS INTEGER.
The is the maximum number of identity resolving keys that are stored in the created whitelist opaque object. Each key is 16 bytes in length. To add a key to this list, use the function BleWhiteListAddIrk().

| Interactive Command | No |

```plaintext
//Example :: BleWhiteListCreate.sb (See in RM1xxCodeSnippets.zip)
DIM hWhiteList : hWhiteList = BleWhiteListCreate(20,10)

IF hWhiteList == 0 THEN
   PRINT "\nWhitelist not created, not enough memory"
ELSE
   PRINT "\nWhitelist created. Handle: "; rc
ENDIF
```

**Expected Output:**

```
Whitelist created. Handle: -1091583777
```

BLEWHITELISTCREATE is an extension function.

**BleWhiteListAddAddr**

**FUNCTION**

This function is used to add a mac address to a whitelist that was created using BleWhiteListCreate() and returns a result code.

Do not attempt to add a resolvable random address. Instead use BleWhiteListAddIrk() and add the identity resolving key for that instead.

**BLEWHITELISTADDDARGS**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>

<tr>
<td><strong>handle</strong></td>
<td>byVAL handle AS INTEGER</td>
</tr>
</tbody>
</table>

This is a handle to the whitelist object that needs to be destroyed and is returned by BleWhiteListCreate().
//Example :: BleWhiteListDestroy.sb (See in RM1xxCodeSnippets.zip)
DIM hWhiteList : hWhiteList = BleWhiteListCreate(20,10)

IF hWhiteList!=0 THEN
    BleWhiteListDestroy(hWhiteList)
    PRINT "\nWhitelist with handle: ";hWhiteList;" destroyed"
ENDIF

Expected Output:

Whitelist with handle: -1091583777 destroyed

Connection Functions

This section describes all the connection manager related routines.

The Bluetooth specification stipulates that a peripheral cannot initiate a connection but can perform disconnections. Only Central Role devices are allowed to connect when an appropriate advertising packet is received from a peripheral.

Events and Messages

See also Events and Messages for BLE-related messages that are thrown to the application when there is a connection or disconnection. The relevant message IDs are (0), (1), (14), (15), (16), (17), (18) and (20):

<table>
<thead>
<tr>
<th>MsgId</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>There is a connection and the context parameter contains the connection handle.</td>
</tr>
<tr>
<td>1</td>
<td>There is a disconnection and the context parameter contains the connection handle.</td>
</tr>
<tr>
<td>14</td>
<td>New connection parameters for connection associated with connection handle.</td>
</tr>
<tr>
<td>15</td>
<td>Request for new connection parameters failed for connection handle supplied.</td>
</tr>
<tr>
<td>16</td>
<td>The connection is to a bonded master</td>
</tr>
<tr>
<td>17</td>
<td>The bonding has been updated with a new long term key</td>
</tr>
<tr>
<td>18</td>
<td>The connection is encrypted</td>
</tr>
<tr>
<td>20</td>
<td>The connection is no longer encrypted</td>
</tr>
</tbody>
</table>

BleConnect

FUNCTION

This function is used to make a connection to a device in peripheral mode which is actively advertising. Note that the peripheral device MUST be advertising with either ADV_IND or ADV_DIRECT_IND type of advert to be able to successfully connect.

When the connection is complete a EVBLEMSG message with msgId = 0 and context containing the handle is thrown to the smartBASIC runtime engine.
If the connection times out, then the event EVBLE_CONN_TIMEOUT is thrown to the smartBASIC application.

When a connection is attempted, there are other parameters that are used and the default values for those are assumed; such as scan window, scan interval, and periodicity. The default values for these can be changed using the BleConnectConfig() function. At any time, the current settings can be obtained via the SYSINFO() command.

**BLECONNECT$$, connTimeoutMs, minConnIntUs, maxConnIntUs, nSuprToutUs $$)**

Returns

INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.

Arguments

**periphAddr$$**

byRef periphAddr$  AS STRING
This is the MAC address of the device to connect to which MUST be properly formatted and is exactly seven bytes long.

**connTimeoutMs**

byVal connTimeoutMs  AS INTEGER.
The length of time in milliseconds of the connection attempt. If it times out, then the event EVBLE_CONN_TIMEOUT is thrown to the smartBASIC application.

**minConnIntUs**

byVal minConnIntUs  AS INTEGER.
The minimum connection interval in microseconds.

**maxConnIntUs**

byVal maxConnIntUs  AS INTEGER.
The maximum connection interval in microseconds.

**nSuprToutUs**

byVal nSuprToutUs  AS INTEGER.
The link supervision timeout for the connection in microseconds.

Interactive Command

No

//Example :: BleConnect.sb (See in RM1xxCodeSnippets.zip)
DIM rc, periphAddr$

'//Scan indefinitely
rc=BleScanStart(0, 0)

IF rc==0 THEN
   PRINT "\nScanning"
ELSE
   PRINT "\nError: "; INTEGER.H'rc
ENDIF

'//This handler will be called when an advert is received
FUNCTION HndlrAdvRpt()
   DIM advData$, nDiscarded, nRssi

'//Read an advert report and connect to the sender
rc=BleScanGetAdvReport(periphAddr$, advData$, nDiscarded, nRssi)
rc=BleScanStop()

'//Connect to device with MAC address obtained above with 5s connection timeout,
'//20ms min connection interval, 75 max, 5 second supervision timeout.
rc=BleConnect(periphAddr$, 5000, 20000, 75000, 5000000)
IF rc==0 THEN
    PRINT "\n--- Connecting"
ELSE
    PRINT "\nError: "; INTEGER.H'rc
ENDIF
ENDFUNC 1

'//This handler will be called in the event of a connection timeout
FUNCTION HndlrConnTO()
    PRINT "\n--- Connection timeout"
    rc=BleScanStart(0, 0)
ENDFUNC 1

'//This handler will be called when there is a BLE message
FUNCTION HndlrBleMsg(nMsgId, nCtx)

ONEVENT EVBLE_CONN_TIMEOUT CALL HndlrConnTO
BLECONNECT is an extension function.

**BleConnectCancel**

**FUNCTION**

This function is used to cancel an ongoing connection attempt which has not timed out. It takes no parameters as there can only be one attempt in progress.

Use the value returned by SYSINFO(2016) to determine if there is an ongoing connection attempt.

The value is a bit mask:

<table>
<thead>
<tr>
<th>Bit 0</th>
<th>Set if advertising is in progress (not possible with the RM1xx)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 1</td>
<td>Set if there is already a connection in peripheral mode (not possible with the RM1xx)</td>
</tr>
<tr>
<td>Bit 2</td>
<td>Set if there is current connection attempt ongoing</td>
</tr>
<tr>
<td>Bit 3</td>
<td>Set when scanning</td>
</tr>
<tr>
<td>Bit 4</td>
<td>Set if there is already a connection to a peripheral</td>
</tr>
</tbody>
</table>

**BLECONNECTCANCEL ()**

- **Returns**: INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.
- **Arguments**: None
- **Interactive Command**: No

//Example :: BleConnectCancel.sb (See in RM1xxCodeSnippets.zip)

```sb
DIM rc, periphAddr$

'//Scan indefinitely
rc=BleScanStart(0, 0)

IF rc==0 THEN
```

```
PRINT "\nScanning"
ELSE
  PRINT "\nError: "; INTEGER.H'rc
ENDIF

'//This handler will be called when an advert is received
FUNCTION HndlrAdvRpt()
    DIM advData$,: nDiscarded,: nRssi

    '//Read an advert report and connect to the sender
    rc=BleScanGetAdvReport(periphAddr$,: advData$,: nDiscarded,: nRssi)
    rc=BleScanStop()

    '//Wait until module stops scanning
    WHILE SysInfo(2016)==8
        ENDWHILE

    '//Connect to device with MAC address obtained above with 5s connection timeout,
    '//20ms min connection interval, 75 max, 5 second supervision timeout.
    rc=BleConnect(periphAddr$: 5000, 20000, 75000, 5000000)
    IF rc==0 THEN
        PRINT "\n--- Connecting \nCancel"
    ELSE
        PRINT "\nError: "; INTEGER.H'rc
    ENDIF

    '//Cancel current connection attempt
    rc=BleConnectCancel()

    PRINT "\n--- Connection attempt cancelled"
ENDFUNC 0

ONEVENT EVBLE_ADV_REPORT CALL HndlrAdvRpt

WAITEVENT
BLECONNECTCANCEL is an extension function.

**BleConnectConfig**

**FUNCTION**

This function is used to modify the default parameters that are used when attempting a connection using BleConnect(). At any time, they can be read by adding the configID to 2100 and then passing that value to SYSINFO().

When connecting, the central device must scan for adverts and then, when the particular peer address is encountered, it can send the connection message to that peripheral.

Therefore, a connection attempt requires the underlying stack API to be supplied with a scan interval and scan window. In addition, when multiple connections are in place, the radio must be shared as efficiently as possible; one scheme to put in place is to have all connections parameters being integer multiples of a ‘base’ value. For the purpose of this documentation and discussions with Laird, this parameter is referred to as ‘multi-link connection interval periodicity’.

The default settings for these parameters are as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multi-link Connection Interval Periodicity</td>
<td>20 milliseconds</td>
</tr>
<tr>
<td>Scan Interval</td>
<td>80 milliseconds</td>
</tr>
<tr>
<td>Scan Window</td>
<td>40 milliseconds</td>
</tr>
<tr>
<td>Scan Latency</td>
<td>0</td>
</tr>
</tbody>
</table>

**Notes:**

- The Scan Window and Interval are multiple integers of the periodicity (but do not have to be) and the scanning has a 50% duty cycle. The 50% duty cycle attempts to ensure that connection events for existing connections are missed as infrequently as possible.
- The Scan Window and Interval are internally stored in units of 0.625 milliseconds slots, therefore reading back via SYSINFO() does not accurately return the value you set.

**BLECONNECTCONFIG(configID,configValue)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Most typical value – 0x0000, indicating a successful operation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>configID</strong></td>
</tr>
</tbody>
</table>

This identifies the value to update as follows:
<table>
<thead>
<tr>
<th>configValue</th>
<th>byVal configValue AS INTEGER.</th>
</tr>
</thead>
<tbody>
<tr>
<td>This contains the new value to set in the parameters identified by configID.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Interactive Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
</tr>

WAITEVENT

Expected Output:

Adverts Started
New Connection 35800
Disconnected 3580

BLEDISCONNECT is an extension function.

**BleSetCurConnParms**

**FUNCTION**

This function triggers an existing connection identified by a handle to have new connection parameters. For example, interval, slave latency and link supervision timeout.

When the request is complete, a EVBLEMSG message with msgId = 14 and context containing the handle is thrown to the smart BASIC runtime engine if it was successful. If the request to change the connection parameters fails, an EVBLEMSG message with msgid = 15 is thrown to the smart BASIC runtime engine.

**BLESETCURCONNPARMS**nConnHandle, nMinIntUs, nMaxIntUs, nSuprToutUs, nSlaveLatency))

**Returns** INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation.

<table>
<thead>
<tr>
<th>Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nConnHandle</td>
<td>byVal nConnHandle AS INTEGER. Specifies the handle of the connection that must have the connection parameters changed.</td>
</tr>
<tr>
<td>nMinIntUs</td>
<td>byVal nMinIntUs AS INTEGER. The minimum acceptable connection interval in microseconds. Valid range is 7500 to 4000000 and it must be less than or equal to nMaxIntUs</td>
</tr>
<tr>
<td>nMaxIntUs</td>
<td>byVal nMaxIntUs AS INTEGER. The maximum acceptable connection interval in microseconds. Valid range is 7500 to 4000000 and it must be less than or equal to nMinIntUs</td>
</tr>
<tr>
<td>nSuprToutUs</td>
<td>byVal nSuprToutUs AS INTEGER. The link supervision timeout for the connection in microseconds. It should be greater than the slave latency times the actual granted connection interval.</td>
</tr>
<tr>
<td>nSlaveLatency</td>
<td>byVal nSlaveLatency AS INTEGER. The number of connection interval polls that the peripheral may ignore. This times the connection interval shall not be greater than the link supervision timeout.</td>
</tr>
</tbody>
</table>

Interactive Command: No

Note: Slave latency is a mechanism that reduces power usage in a peripheral device and maintains short latency. Generally, a slave reduces power usage by setting the largest connection interval possible. This means the latency is equivalent to that connection interval. To mitigate this, the peripheral can greatly reduce the connection interval and then have a non-zero slave latency.

For example, a keyboard could set the connection interval to 1000 millisecond and slave latency to 0. In this case, key presses are reported to the central device once per second, a poor user experience. Instead, the connection interval can be set to e.g. 50 msec and slave latency to 19. If there are no key presses, the power use is the same as before because ((19+1) * 50) equals 1000. When a key is pressed, the peripheral knows that the central device polls within 50 msec, so it can send that keypress with a latency of 50 msec. A connection interval of 50 and slave latency of 19 means the slave is allowed to NOT acknowledge a poll for up to 19 poll messages from the central device.

New conn Supervision Timeout 4000000
New conn Slave Latency  19
--- Disconnected : 134
```

**Note:** First set of parameters differ depending on your central device.

BLESETCURCONNPARMS is an extension function.

**BleGetCurConnParms**

**FUNCTION**

This function gets the current connection parameters for the connection identified by the connection handle. Given there are three connection parameters, the function takes three variables by reference so that the function can return the values in those variables.

**BLEGETCURCONNPARMS**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Most typical value – 0x0000, indicating a successful operation.</td>
</tr>
</tbody>
</table>

| Arguments |
|-----------|----------------------|
|           |                      |
**BleGetConnHandleFromAddr**

**FUNCTION**

Given a seven-byte Bluetooth MAC address in Little Endian format (the first byte is the type and the second byte is the most significant byte of the six-byte MAC address) this function returns a valid connection handle in the `nConnHandle` argument if a connection exists and an invalid one if there isn’t.

**BLEGETCONNHANDLEFROMADDR(addr$, nConnHandle)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Typical value: 0x0000 (indicates a successful operation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>arguments</td>

<tr>
<td><code>addr$</code></td>
<td>byRef <code>addr$</code> AS STRING This is a 7-byte string which must be a valid 7-byte mac address.</td>
</tr>
<tr>
<td><code>nConnHandle</code></td>
<td>byRef <code>nConnHandle</code> AS INTEGER. The connection handle will be returned in this argument. Will be an invalid handle value if a connection does not exist.</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

```plaintext
DIM addr$ : addr$=""
DIM rc, connHandle

addr$ = "\00\00\01\64\01\02\03"
rc = BleConnHandleFromAddr(addr$, connHandle)
PRINT "\nConnection Handle = "; integer.h’ connHandle
```
Expected Output:

```plaintext
Connection Handle = 0001FF00
```

BLEGETCONNHANDLEFROMADDR is an extension function.

**BleGetAddrFromConnHandle**

**FUNCTION**

Given a valid connection handle, a seven byte Bluetooth MAC address in Little Endian format (the first byte is the type and the second byte is the most significant byte of the six-byte MAC address) is returned which is the Bluetooth address of the connected device.

**BLEGETADDRFROMCONNHANDLE (nConnHandle, addr$)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Typical value:</strong></td>
<td>0x0000 (indicates a successful operation)</td>
</tr>
</tbody>
</table>

**Arguments**

- **nConnHandle**
  - byVal **nConnHandle** AS INTEGER.
  - The connection handle for the connection for which the connected device address is to be returned. Note this will be a resolvable address in the case of say iOS devices.

- **addr$**
  - byRef **addr$** AS STRING
  - The 7-byte string will contain a valid 7-byte mac address if the connection handle provided is for a valid connection.

**Interactive Command**

```basic
DIM addr$ : addr$=""
DIM rc, connHandle

connHandle = 0x0001FF00
rc = BleAddrFromConnHandle (connHandle , addr$)
PRINT ":\Address = ";StrHexize$(addr$)
```

**Expected Output:**

```plaintext
Address = 00000164010203
```

BLEGETADDRFROMCONNHANDLE is an extension function.
Security Manager Functions

This section describes routines which manage all aspects of BLE security such as saving, retrieving, and deleting link keys and creation of those keys using pairing and bonding procedures.

Events and Messages

The following security manager messages are thrown to the run-time engine using the EVBLEMSG message with msgIDs as follows:

<table>
<thead>
<tr>
<th>MsgId</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>Pairing in progress and display Passkey supplied in msgCtx.</td>
</tr>
<tr>
<td>10</td>
<td>A new bond has been successfully created.</td>
</tr>
<tr>
<td>11</td>
<td>Pairing in progress and authentication key requested. Type of key is in msgCtx. msgCtx is 1 for passkey_type which is a number in the range 0 to 999999 and 2 for OOB key which is a 16-byte key.</td>
</tr>
</tbody>
</table>

To submit a passkey, use the function BLESECMPASSKEY.

BleSecMngrPasskey

FUNCTION

This function submits a passkey to the underlying stack during a pairing procedure when prompted by the EVBLEMSG with msgld set to 11. See Events and Messages.

BLESECMPASSKEY(connHandle, nPassKey)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>connHandle byVal connHandle AS INTEGER. This is the connection handle as received via the EVBLEMSG event with msgld set to 0.</td>
</tr>
<tr>
<td></td>
<td>nPassKey byVal nPassKey AS INTEGER. This is the passkey to submit to the stack. Submit a value outside the range 0 to 999999 to reject the pairing.</td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

//Example :: BleSecMngrPasskey.sb (See in RM1xxCodeSnippets.zip)

```plaintext
DIM rc, connHandle
DIM addr$ : addr$=""

FUNCTION HandlerBleMsg(BYVAL nMsgId AS INTEGER, BYVAL nCtx AS INTEGER) AS INTEGER
SELECT nMsgId
    CASE 0
        connHandle = nCtx
```

PRINT BleSecMngrKeySizes(8,15)

Expected Output:

```
0
```

BLESECMGRKEYSIZES is an extension function.

BleSecMngrIoCap

FUNCTION

This function sets the user I/O capability for subsequent pairings and is used to determine if the pairing is authenticated. This is related to Simple Secure Pairing as described in the following whitepapers:

In addition, the “Security Manager Specification” in the core 4.0 specification Part H provides a full description.

You must be registered with the Bluetooth SIG (www.bluetooth.org) to get access to all these documents.

An authenticated pairing is deemed to be one with less than 1 in a million probability that the pairing was compromised by a MITM (Man in the middle) security attack.

The valid user I/O capabilities are as described below.
**BLESECMNGRIOCAPnIoCap)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>

```plaintext
//Example :: BleSecMngrIoCap.sb (See in RM1xxCodeSnippets.zip)
PRINT BleSecMngrIoCap(1)
```

**Expected Output:**

```
0
```

BLESECMNGRIOCAP is an extension function.

**BleSecMngrBondReq**

**FUNCTION**

This function is used to enable or disable bonding when pairing.

**Note:** This function will be deprecated in future releases. It is recommended to invoke this function, with the parameter set to 0, before calling BleAuthenticate().

**BLESECMNGRGBONDREQnBondReq)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments nBondReq</td>
<td>byVal nBondReq AS INTEGER.</td>

//Example :: BleSecMngrBondReq.sb (See in RM1xxCodeSnippets.zip)
IF BleSecMngrBondReq(0)==0 THEN
  PRINT "\nBonding disabled"
ENDIF

Expected Output:

Bonding disabled

**BLESECNMGRBONDREQ** is an extension function.

**BlePair**

**FUNCTION**

This routine is used to start a pairing procedure with the peer. It will result in various EVBLEMSG events, such as:

<table>
<thead>
<tr>
<th>Message ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLE_EVBLEMSGID_NEW_BOND</td>
<td>messageId = 10</td>
</tr>
<tr>
<td>BLE_EVBLEMSGID_AUTH_KEY_REQUEST</td>
<td>messageId = 11</td>
</tr>
<tr>
<td>BLE_EVBLEMSGID_UPDATED_BOND</td>
<td>messageId = 17</td>
</tr>
<tr>
<td>BLE_EVBLEMSGID_ENCRYPTED</td>
<td>messageId = 18</td>
</tr>
</tbody>
</table>

If the pairing fails for any reason, then the connection is dropped.

**BLEPAIR (nAppConnHandle, nPairType)**

**Returns**

INTEGER, a result code.

**Typical value:** 0x0000 (indicates a successful operation)

**Arguments**

<table>
<thead>
<tr>
<th>nAppConnHandle</th>
<th>byVal nAppConnHandle AS INTEGER. This is the connection handle for the device that should be paired.</th>
</tr>
</thead>
<tbody>
<tr>
<td>nPairType</td>
<td>0 Bonding is not performed therefore the connection enters encryption but keys are not exchanged for future use.</td>
</tr>
<tr>
<td></td>
<td>1 Bonding id forced (phase 3 of the pairing procedure as described in the Bluetooth specification) which means any exchanged keys are stored in the bonding manager database.</td>
</tr>
<tr>
<td></td>
<td>Not 0 or 1 The type of bonding is dictated by the default setting which is set by the function BleSecMngrBondReq.</td>
</tr>
</tbody>
</table>

**Interactive Command**

No

See example for **BleDisconnect**:

Change "rc = BlePair(nCtx)" to "PRINT BlePair(nCtx)"

**BLEPAIR** is an extension function.
BleAuthenticate

FUNCTION

This function is internally the same as BlePair(), see details of that function, and exists for legacy reasons only.

GATT Server Functions

This section describes all functions related to creating and managing services that collectively define a GATT table from a GATT server role perspective. These functions allow the developer to create any service that has been described and adopted by the Bluetooth SIG or any custom service that implements some custom unique functionality, within resource constraints such as the limited RAM and FLASH memory that is exist in the module.

A GATT table is a collection of adopted or custom Services which in turn are a collection of adopted or custom characteristics. Although, by definition an adopted service cannot contain custom characteristics but the reverse is possible where a custom service can include both adopted and custom characteristics.

Descriptions of services and characteristics are available in the Bluetooth Specification v4.0 or newer and like most specifications are concise and difficult to understand. What follows is an attempt to familiarize the reader with those concepts using the perspective of the smartBASIC programming environment.

To help understand the terms services and characteristics better, think of a characteristic as a container (or a pot) of data where the pot comes with space to store the data and a set of properties that are officially called descriptors in the BT spec. In the pot analogy, think of descriptor as color of the pot, whether it has a lid, whether the lid has a lock or whether it has a handle or a spout, etc. For a full list of these descriptors, see the Bluetooth SIG website. These descriptors are assigned 16 bit UUIDs (value 0x29xx) and are referenced in some of the smartBASIC API functions if you decide to add those to your characteristic definition.

To wrap up the loose analogy, think of service as just a carrier bag to hold a group of related characteristics together where the printing on the carrier bag is a UUID. You will find that from a smartBASIC developer’s perspective, a set of characteristics is what you need to manage and the concept of service is only required at GATT table creation time.

A GATT table can have many services each containing one or more characteristics. The differentiation between services and characteristics is expedited using an identification number called a UUID (Universally Unique Identifier) which is a 128 bit (16 byte) number. Adopted services or characteristics have a 16 bit (2 byte) shorthand identifier (which is just an offset plus a base 128 bit UUID defined and reserved by the Bluetooth SIG) and custom service or characteristics shall have the full 128 bit UUID. The logic behind this is that when you come across a 16 bit UUID, it implies that a specification is published by the Bluetooth SIG whereas using a 128 bit UUID does NOT require any central authority to maintain a register of those UUIDs or specifications describing them.

The lack of requirement for a central register is important to understand, in the sense that if a custom service or characteristic needs to be created, the developer can use any publicly available UUID (sometimes also known as GUID) generation utility.
These utilities use entropy from the real world to generate a 128-bit random number that has an extremely low probability to be the same as that generated by someone else at the same time or in the past or future.

As an example, at the time of writing this document, the following website http://www.guidgenerator.com/online-guid-generator.aspx offers an immediate UUID generation service, although it uses the term GUID. From the GUID Generator website:

How unique is a GUID?

128-bits is big enough and the generation algorithm is unique enough that if 1,000,000,000 GUIDs per second were generated for 1 year the probability of a duplicate would be only 50%. Or if every human on Earth generated 600,000,000 GUIDs there would only be a 50% probability of a duplicate.

This extremely low probability of generating the same UUID is why there is no need for a central register maintained by the Bluetooth SIG for custom UUIDs.

Note that Laird does not warrant or guarantee that the UUID generated by this website or any other utility is unique. It is left to the judgement of the developer whether to use it or not.

Note: If the developer does intend to create custom services and/or characteristics then it is recommended that a single UUID is generated and be used from then on as a 128 bit (16 byte) company/developer unique base along with a 16 bit (2 byte) offset, in the same manner as the Bluetooth SIG.

This allows up to 65536 custom services and characteristics to be created with the added advantage that it is easier to maintain a list of 16-bit integers.

The main reason for avoiding more than one long UUID is to keep RAM usage down given that 16 bytes of RAM is used to store a long UUID. smartBASIC functions are provided to manage these custom 2-byte UUIDs along with their 16-byte base UUIDs.

In this document when a service or characteristic is described as adopted, it implies that the Bluetooth SIG has published a specification which defines that service or characteristic and there is a requirement that any device claiming to support them SHALL have approval to prove that the functionality has been tested and verified to behave as per that specification.

Currently there is no requirement for custom service and/or characteristics to have any approval. By definition, interoperability is restricted to just the provider and implementer.

A service is an abstraction of some collectivized functionality which, if broken down further into smaller components, would cease to provide the intended behavior. A couple of examples in the BLE domain that have been adopted by the Bluetooth SIG are Blood Pressure Service and Heart Rate Service. Each have sub-components that map to characteristics.

Blood pressure is defined by a collection of data entities like for example Systolic Pressure, Diastolic Pressure, Pulse Rate, and many more. Likewise, a Heart Rate service also has a collection which includes entities such as the Pulse Rate and Body Sensor Location.
A list of all the adopted Services is at: http://developer.bluetooth.org/gatt/services/Pages/ServicesHome.aspx. Laird recommends that if you decide to create a custom service then it is defined and described in a similar fashion, so that your goal should be to get the Bluetooth SIG to adopt it for everyone to use in an interoperable manner.

These services are also assigned 16 bit UUIDs (value 0x18xx) and are referenced in some of the smartBASIC API functions described in this section.

Services, as described above, are a collection of one or more characteristics. A list of all adopted characteristics is found at http://developer.bluetooth.org/gatt/characteristics/Pages/CharacteristicsHome.aspx. You should note that these descriptors are also assigned 16 bit UUIDs (value 0x2Axx) and are referenced in some of the API functions described in this section. Custom characteristics have 128 bit (16 byte) UUIDs and API functions are provided to handle those.

**Note:** If you intend to create a custom service or characteristic, and adopt the recommendation, stated above, of a single long 16-byte base UUID, so that the service can be identified using a 2 byte UUID, then allocate a 16-bit value which is not going to coincide with any adopted values to minimise confusion. Selecting a similar value is possible and legal given that the base UUID is different. The recommendation is just for ease of maintenance.

Finally, having prepared a background to services and characteristics, the rest of this introduction will focus on the specifics of how to create and manage a GATT table from a perspective of the smartBASIC API functions in the module.

Recall that a service has been described as a carrier bag that groups related characteristics together and a characteristic is just a data container (pot). Therefore, a remote GATT client, looking at the server, which is presented in your GATT table, sees multiple carrier bags each containing one or more pots of data.

The GATT client (remote end of the wireless connection) needs to see those carrier bags to determine the groupings and once it has identified the pots it will only need to keep a list of references to the pots it is interested in. Once that list is made at the client end, it can ‘throw away the carrier bag’.

Similarly, in the module, once the GATT table is created and after each Service is fully populated with one or more characteristics there is no need to keep that ‘carrier bag’. However, as each characteristic is ‘placed in the carrier bag’ using the appropriate smartBASIC API function, a ‘receipt’ will be returned and is referred to as a char_handle. The developer will then need to keep those handles to be able to read and write and generally interact with that particular characteristic. The handle does not care whether the Characteristic is adopted or custom because from then on the firmware managing it behind the scenes in smartBASIC does not care.
Therefore, from the smartBASIC app developer’s logical perspective a GATT table looks nothing like the table that is presented in most BLE literature. Instead the GATT table is purely and simply just a collection of char_handles that reference the characteristics (data containers) which have been registered with the underlying GATT table in the BLE stack.

A particular char_handle is in turn used to make something happen to the referenced characteristic (data container) using a smartBASIC function and conversely if data is written into that characteristic (data container), by a remote GATT Client, then an event is thrown, in the form of a message, into the smartBASIC runtime engine which will get processed if and only if a handler function has been registered by the apps developer using the ONEVENT statement.

With this simple model in mind, an overview of how the smartBASIC functions are used to register Services and Characteristics is illustrated in the flowchart on the right and sample code follows on the next page.
//Example :: ServicesAndCharacteristics.sb (See in RM1xxCodeSnippets.zip)

//Register two Services in the GATT Table. Service 1 with 2 Characteristics and Service 2 with 1 characteristic. This implies a total of 3 characteristics to manage.
//The characteristic 2 in Service 1 will not be readable or writable but only indicatable
//The characteristic 1 in Service 2 will not be readable or writable but only notifyable
//==============================================================================

//===The 2 services are now visible in the gatt table.

//--To deal with writes from a gatt client into characteristic 1 of Service 1
//--which has the handle hChar11

//-- This handler is called when there is a EVCHARVAL message
FUNCTION HandlerCharVal(BYVAL hChar AS INTEGER) AS INTEGER
RM1xx Series smartBASIC Extensions
User Guide

DIM attr$

IF hChar == hChar11 THEN
    rc = BleCharValueRead(hChar11,attr$)
    print "Svc1/Char1 has been written with = ";attr$

ENDIF
ENDFUNC 1

// enable characteristic value write handler
OnEvent EVCHARVAL call HandlerCharVal

WAITEVENT

Assuming there is a connection and notify has been enabled then a value notification is expedited as follows:

// notify a value for characteristic 1 in service 2

attr$="somevalue"
rc = BleCharValueNotify(hChar12,attr$)

Assuming there is a connection and indicate has been enabled then a value indication is expedited as follows:

// indicate a value for characteristic 2 in service 1

// This handler is called when there is a EVCHARHVC message

FUNCTION HandlerCharHvc(BYVAL hChar AS INTEGER) AS INTEGER
    IF hChar == hChar12 THEN
        PRINT "Svc1/Char2 indicate has been confirmed"
    ENDIF
ENDFUNC 1

// enable characteristic value indication confirm handler
OnEvent EVCHARHVC CALL HandlerCharHvc

attr$="somevalue"
rc = BleCharValueIndicate(hChar12,attr$)

The rest of this section details all the smartBASIC functions that help create that framework.
Events and Messages

See also Events and Messages for the messages that are thrown to the application which are related to the generic characteristics API. The relevant messages are those that start with EVCHARxxx.

BleGapSvcInit

FUNCTION

This function updates the GAP service, which is mandatory for all approved devices to expose, with the information provided. If it is not called before adverts are started, default values are exposed. Given this is a mandatory service, unlike other services which need to be registered, this one must only be initialized as the underlying BLE stack unconditionally registers it when starting up.

The GAP service contains five characteristics as listed at the following website:

A central only role module will never be a peripheral so the ‘Peripheral Preferred Connection Parameters’ characteristic, which is optional will not be exist and so the last four parameters of this function are ignored and exist only to maintain compatibility with the RM1xx firmware. In future when 4.1 compatible firmware is available it will make sense again.

ENDIF
```

Expected Output:

Success

BLESVCREGDEVINFO is an extension function.
BleHandleUuid16

FUNCTION

This function takes an integer in the range 0 to 65535 and converts it into a 32-bit integer handle that associates the integer as an offset into the Bluetooth SIG 128 bit (16byte) base UUID which is used for all adopted services, characteristics and descriptors.

If the input value is not in the valid range, then an invalid handle (0) is returned.

The returned handle shall be treated by the developer as an opaque entity and no further logic shall be based on the bit content, apart from all 0s which represents an invalid UUID handle.

BLEHANDLEUUID16(nUuid16)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a nonzero handle shorthand for the UUID. Zero is an invalid UUID handle.</th>
</tr>
</thead>
<tbody>
<tr>

No

//Example :: BleHandleUuid16.sb (See in RM1xxCodeSnippets.zip)
DIM uuid
DIM hUuidHRS

uuid = 0x180D //this is UUID for Heart Rate Service
hUuidHRS = BleHandleUuid16(uuid)
IF hUuidHRS == 0 THEN
  PRINT "\nFailed to create a handle"
ELSE
  PRINT "Handle for HRS Uuid is "; integer.h' hUuidHRS;'(";hUuidHRS;")"
ENDIF

Expected Output:

Handle for HRS Uuid is FE01180D (-33482739)

BLEHANDLEUUID16 is an extension function.
BleHandleUuid128

FUNCTION

This function takes a 16-byte string and converts it into a 32-bit integer handle. The handle consists of a 16-bit (two byte) offset into a new 128-bit base UUID.

The base UUID is basically created by taking the 16-byte input string and setting bytes 12 and 13 to zero after extracting those bytes and storing them in the handle object. The handle also contains an index into an array of these 16-byte base UUIDs which are managed opaquely in the underlying stack.

The returned handle shall be treated by the developer as an opaque entity and no further logic shall be based on the bit content. However, note that a string of zeroes represents an invalid UUID handle.

Please ensure that you use a 16 byte UUID that has been generated using a random number generator with sufficient entropy to minimize duplication, as stated in an earlier section and that the first byte of the array is the most significant byte of the UUID.

BleHandleUuid128(stUuid$)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a handle representing the shorthand UUID. If zero, which is an invalid UUID handle, there is either no spare RAM memory to save the 16-byte base or more than 253 custom base UUIDs have been registered.</th>
</tr>
</thead>
</table>
| Arguments stUuid$ | byRef stUuid$ AS STRING  
Any 16-byte string that was generated using a UUID generation utility that has enough entropy to ensure that it is random. The first byte of the string is the MSB of the UUID – that is, big endian format. |

Interactive Command | No |

//Example :: BleHandleUuid128.sb (See in RM1xxCodeSnippets.zip)
DIM uuid$, hUuidCustom

// create a custom uuid for my ble widget
uuid$ = "ced9d91366924a1287d56f2764762b2a"
uuid$ = StrDehexize$(uuid$)
hUuidCustom = BleHandleUuid128(uuid$)
IF hUuidCustom = 0 THEN
    PRINT "\nFailed to create a handle"
ELSE
    PRINT "Handle for custom Uuid is "; integer.h’ hUuidCustom; "(";hUuidCustom;")"
ENDIF
// hUuidCustom now references an object which points to
// a base uuid = ced9d91366924a1287d56f27476722b2a (note 0's in byte position 2/3)
// and an offset = 0xd913

Expected Output:

Handle for custom Uuid is FC03D913 (-66856685)

BLEHANDLEUUID128 is an extension function.

**BleHandleUuidSibling**

**FUNCTION**

This function takes an integer in the range 0 to 65535 along with a UUID handle which had been previously created using BleHandleUuid16() or BleHandleUuid128() to create a new UUID handle. This handle references the same 128 base UUID as the one referenced by the UUID handle supplied as the input parameter.

The returned handle shall be treated by the developer as an opaque entity and no further logic shall be based on the bit content, apart from all 0s which represents an invalid UUID handle.

**BLEHANDLEUUIDSIBLING(nUuidHandle, nUuid16)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a handle representing the shorthand UUID and can be zero which is an invalid UUID handle, if nUuidHandle is an invalid handle in the first place.</th>
</tr>

IF hUuid1 == 0 THEN
   PRINT "\nFailed to create a handle"
ELSE
BLEHANDLEUUIDSIBLING is an extension function.

**BleSvcCommit**

This function is now deprecated. Use `BleServiceNew()` & `BleServiceCommt()` instead.

**BleServiceNew**

**FUNCTION**

As explained in an earlier section, a service in the context of a GATT table is just a collection of related characteristics. This function is used to inform the underlying GATT table manager that one or more related characteristics are going to be created and installed in the GATT table and that until the next call of this function they shall be associated with the service handle that it provides upon return of this call.

Under the hood, this call results in a single attribute being installed in the GATT table with a type signifying a PRIMARY or a SECONDARY service. The value for this attribute is the UUID that identifies this service and in turn is precreated using one of these functions: `BleHandleUuid16()`, `BleHandleUuid128()`, or `BleHandleUuidSibling()`.

Note that when a GATT Client queries a GATT server for services over a BLE connection, it only receives a list of PRIMARY services. SECONDARY services are a mechanism for multiple PRIMARY services to reference single instances of shared characteristics that are collected in a SECONDARY service. This
referencing is expedited within the definition of a service using the concept of INCLUDED SERVICE which itself is just an attribute that is grouped with the PRIMARY service definition. An Included Service is expedited using the function BleSvcAddIncludeSvc() which is described immediately after this function.

This function now replaces BleSvcCommit() and marks the beginning of a service definition in the GATT server table. When the last descriptor of the last characteristic has been registered the service definition should be terminated by calling BleServiceCommit().

BLESERVICENEW(nSvcType, nUuidHandle, hService ))

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
</table>
| nSvcType | byVal nSvcType  AS INTEGER
This will be 0 for a SECONDARY service and 1 for a PRIMARY service and all other values are reserved for future use and will result in this function failing with an appropriate result code. |
| nUuidHandle | byVal nUuidHandle  AS INTEGER
This is a handle to a 16 bit or 128 bit UUID that identifies the type of Service function provided by all the Characteristics collected under it. It will have been pre-created using one of the three functions: BleHandleUuid16(), BleHandleUuid128() or BleHandleUuidSibling() |
| hService | byRef hService  AS INTEGER
If the Service attribute is created in the GATT table then this will contain a composite handle which references the actual attribute handle. This is then subsequently used when adding Characteristics to the GATT table. If the function fails to install the Service attribute for any reason this variable will contain 0 and the returned result code will be non-zero. |

Interactive Command

No

This function is used to add a reference to a service within another service. This is usually, but not necessarily, a SECONDARY service which is virtually identical to a PRIMARY service from the GATT server perspective and the only difference is that when a GATT client queries a device for all services it does not get any mention of SECONDARY services.

When a GATT client encounters an INCLUDED SERVICE object when querying a particular service, it performs a sub-procedure to get handles to all the characteristics that are part of that INCLUDED service.

This mechanism is provided to allow for a single set of characteristics to be shared by multiple primary services. This is most relevant if a characteristic is defined so that it can have only one instance in a GATT table but needs to be offered in multiple PRIMARY services. Hence a typical implementation, where a characteristic is part of many PRIMARY services, installs that characteristic in a SECONDARY service (see BleSvcCommit() ) and then uses the function defined in this section to add it to all the PRIMARY services that want to have that characteristic as part of their group.

It is possible to include a service which is also a PRIMARY or SECONDARY service, which in turn can include further PRIMARY or SECONDARY services. The only restriction to nested includes is that there cannot be recursion.

Further note that if a service has INCLUDED services, then they are installed in the GATT table immediately after a service is created using BleSvcCommit() and before BleCharCommit(). The BT 4.0 specification mandates that any Included Service attribute is present before any characteristic attributes within a particular service group declaration.
BleSvcAddIncludeSvc is an extension function.

**BleAttrMetadata**

**FUNCTION**

A GATT table is an array of attributes which are grouped into characteristics which in turn are further grouped into services. Each attribute consists of a data value which can be anything from 1 to 512 bytes long according to the specification and properties such as read and write permissions, authentication, and security properties. When services and characteristics are added to a GATT server table, multiple attributes with appropriate data and properties are added.
This function allows a 32-bit integer to be created (an opaque object) which defines those properties and is then submitted along with other information to add the attribute to the GATT table.

When adding a service attribute (not the whole service, in this context), the properties are defined in the BT specification so that it is open for reads without any security requirements but cannot be written and always has the same data content structure. This implies that a metadata object does NOT need to be created.

However, when adding characteristics, which consists of a minimum of two attributes, one similar in function as the aforementioned service attribute and the other the actual data container, then properties for the value attribute must be specified. Here, properties refers to properties for the attribute, not properties for the characteristic container as a whole. These also exist and must be specified, but that is done in a different manner as explained later.

For example, the value attribute must be specified for read/write permission and whether it needs security and authentication to be accessed.

If the characteristic is capable of notification and indication, the client must be able to enable or disable it. This is done through a Characteristic Descriptor, another attribute. The attribute also needs to have a metadata supplied when the characteristic is created and registered in the GATT table. This attribute, if it exists, is called a Client Characteristic Configuration Descriptor (CCCD). A CCCD always has two bytes of data and currently only two bits are used as on/off settings for notification and indication.

A characteristic can also be capable of broadcasting its value data in advertisements. For the GATT client to be able to control this, there is another type of Characteristic Descriptor which also needs a metadata object to be supplied when the characteristic is created and registered in the GATT table. This attribute, if it exists, is called a Server Characteristic Configuration Descriptor (SCCD). A SCCD always has two bytes of data and currently only one bit is used as on/off settings for broadcasts.

Finally, if the characteristic has other descriptors to qualify its behavior, a separate API function is also supplied to add that to the GATT table and when setting up a metadata object must be supplied.

In a nutshell, think of a metadata object as a note to define how an attribute behaves and the GATT table manager needs that before it is added. Some attributes have those ‘notes’ specified by the BT specification and so the GATT table manager does not need to be provided with any, but the rest require it.

This function helps write that metadata.

BLEATTRMETADATA(nReadRights, nWriteRights, nMaxDataLen, fIsVariableLen, resCode))

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a 32-bit opaque data object to be used in subsequent calls when adding characteristics to a GATT table.</th>
</tr>
</thead>
</table>
| Arguments | **nReadRights** byVal nReadRights AS INTEGER  
This specifies the read rights and shall have one of the following values:  
0 | No access  
1 | Open  
2 | Encrypted with no Man-in-the-Middle (MITM) protection  
3 | Encrypted with MITM protection  
4 | Signed with MITM protection (not available) |
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>nWriteRights</strong></td>
<td><strong>byVal nWriteRights AS INTEGER</strong></td>
</tr>
<tr>
<td></td>
<td>This specifies the write rights and shall have one of the following values:</td>
</tr>
<tr>
<td>5</td>
<td>Signed with MITM protection (not available)</td>
</tr>
<tr>
<td><strong>Note:</strong> In early releases of the firmware, 4 and 5 are not available.</td>
<td></td>
</tr>
</tbody>
</table>

| **nMaxDataLen** | **byVal nMaxDataLen AS INTEGER** |
|                 | This specifies the maximum data length of the VALUE attribute. Range is from 1 to 512 bytes according to the BT specification; the stack implemented in the module may limit it for early versions. |
|                 | At the time of writing, the limit is 20 bytes. |

| **fIsVariableLen** | **byVal fIsVariableLen AS INTEGER** |
|                   | Set this to non-zero only if you want the attribute to automatically shorten its length according to the number of bytes written by the client. |
|                   | For example, if the initial length is two and the client writes one byte, then if this is 0, only the first byte is updated and the rest remains unchanged. |
|                   | If this parameter is set to one, then when a single byte is written the attribute shortens its length to accommodate. If the client tries to write more bytes than the initial maximum length, then the client receives an error response. |

| **resCode** | **byRef resCode AS INTEGER** |
|            | This variable will be updated with result code which will be 0 if a metadata object was successfully returned by this call. Any other value implies a metadata object did not get created. |

Interactive Command  No

//Example :: BleAttrMetadata.sb (See in RM1xxCodeSnippets.zip)

DIM mdVal //metadata for value attribute of Characteristic

//++++
// Create the metadata for the value attribute in the characteristic
// and Heart Rate attribute has variable length
//++++
//There is always a Value attribute in a characteristic
mdVal=bleAttrMetadata(17,0,20,0,rc)
//There is a CCCD and SCCD in this characteristic
mdCccd=bleAttrMetadata(1,2,2,0,rc)
mdSccd=bleAttrMetadata(0,0,2,0,rc)

//Create the Characteristic object
IF BleCharNew(3,BleHandleUuid16(0x2A1C),mdVal,mdCccd,mdSccd)==0 THEN
    PRINT "\nSuccess"
ELSE
    PRINT "\nFailed"
ENDIF

Expected Output:
Success

BLEATTRMETADATA is an extension function.

BleCharNew

FUNCTION

When a characteristic is to be added to a GATT table, multiple attribute ‘objects’ must be precreated. After they are all created successfully, they are committed to the GATT table in a single atomic transaction.

This function is the first function that is called to start the process of creating those multiple attribute ‘objects’. It is used to select the characteristic properties (which are distinct and different from attribute properties), the UUID to be allocated for it and then up to three metadata objects for the value attribute, and CCCD/SCCD Descriptors respectively.

BleCharNew(nCharProps, nUuidHandle, mdVal, mdCccd, mdSccd))

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
</table>
| Arguments | byVal nCharProps AS INTEGER
This variable contains a bit mask to specify the following high level properties for the characteristic that is added to the GATT table: |
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Broadcast capable (SCCD descriptor must be present)</td>
</tr>
<tr>
<td>1</td>
<td>Can be read by the client</td>
</tr>
<tr>
<td>2</td>
<td>Can be written by the client without response</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>3</td>
<td>Can be written</td>

<tr>
<td>4</td>
<td>Can be notifiable (CCCD descriptor must be present)</td>
</tr>
<tr>
<td>5</td>
<td>Can be indicatable (CCCD descriptor must be present)</td>
</tr>
<tr>
<td>6</td>
<td>Can accept signed writes</td>
</tr>
<tr>
<td>7</td>
<td>Reliable writes</td>
</tr>
</tbody>
</table>

**nUuidHandle**

*byVal nUuidHandle AS INTEGER*

This specifies the UUID that is allocated to the characteristic – either 16 or 128 bits. This variable is a handle, pre-created using one of the following functions:

- BleHandleUuid16()
- BleHandleUuid128()
- BleHandleUuidSibling()

**mdVal**

*byVal mdVal AS INTEGER*

This is the mandatory metadata that is used to define the properties of the Value attribute that is created in the characteristic and is pre-created using the help of the function BleAttrMetadata().

**mdCccd**

*byVal mdCccd AS INTEGER*

This is an optional metadata that is used to define the properties of the CCCD descriptor attribute that is created in the characteristic and is pre-created using the help of the function BleAttrMetadata() or set to 0 if CCCD is not to be created. If nCharProps specifies that the characteristic is notifiable or indicatable and this value contains 0, this function aborts with an appropriate result code.

**mdSccd**

*byVal mdSccd AS INTEGER*

This is an optional metadata that is used to define the properties of the SCCD descriptor attribute that is created in the characteristic and is pre-created using the help of the function BleAttrMetadata() or set to 0 if SCCD is not to be created. If nCharProps specifies that the characteristic is broadcastable and this value contains 0, this function aborts with an appropriate result code.

### Interactive Command

No

```plaintext
// Example :: BleCharNew.sb (See in RM1xxCodeSnippets.zip)
DIM rc
DIM charUuuid : charUuuid = BleHandleUuid16(2)  //Characteristic's UUID
DIM mdVal : mdVal = BleAttrMetadata(1,0,20,0,rc)  //Metadata for value attribute
DIM mdCccd : mdCccd = BleAttrMetadata(1,1,2,0,rc)  //Metadata for CCCD attribute of Characteristic

//==============================================================================
// Create a new char:
// --- Indicatable, not Broadcastable (so mdCccd is included, but not mdSccd)
// --- Can be read, not written (shown in mdVal as well)
//==============================================================================
```
BLECHARNEW is an extension function.

**BleCharDescUserDesc**

**FUNCTION**

This function adds an optional User Description descriptor to a characteristic and can only be called after BleCharNew() has started the process of describing a new characteristic.

The BT 4.0 specification describes the User Description descriptor as “... a UTF-8 string of variable size that is a textual description of the characteristic value.” It further stipulates that this attribute is optionally writable and so a metadata argument exists to configure it to be so. The metadata automatically updates the Writable Auxiliaries properties flag for the characteristic. This is why that flag bit is NOT specified for the nCharProps argument to the BleCharNew() function.

**BLECHARDESCUSERDESC(userDesc$, mdUser )**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Most typical value – 0x0000, indicating a successful operation.</td>

<th>Arguments</th>
<th>byRef userDesc$ AS STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>userDesc$</td>
<td>The user description string with which to initialise the descriptor. If the length of the string exceeds the maximum length of an attribute, then this function aborts with an error result code.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>mdUser</th>
<th>byVal mdUser AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>mdUser</td>
<td>This is a mandatory metadata that defines the properties of the User Description descriptor attribute created in the characteristic and pre-created using the help of BleAttrMetaData(). If the write rights are set to one or greater, the attribute is marked as writable and the client is able to provide a user description that overwrites the one provided in this call.</td>
</tr>
</tbody>
</table>

**Interactive Command**

No

```plaintext
//Example :: BleCharDescUserDesc.sb (See in RM1xxCodeSnippets.zip)
DIM rc, metaSuccess,usrDesc$ : usrDesc$="A description"
DIM charUuid : charUuid = BleHandleUuid16(1)
DIM charMet : charMet = BleAttrMetaData(1,1,20,0,metaSuccess)
DIM mdUsrDsc : mdUsrDsc = BleAttrMetaData(1,1,20,0,metaSuccess)
```

```plaintext
IF BleCharNew(0x22,charUuid,mdVal,mdCccd,0)==0 THEN
    PRINT "\nNew Characteristic created"
ELSE
    PRINT "\nFailed"
ENDIF
```
DIM mdSccd : mdSccd = BleAttrMetadata(1,1,2,0,rc) //CCCD metadata for char

//initialise char, write/read enabled, accept signed writes, indicatable
rc=BleCharNew(0x4B, charUuid, charMet, 0, mdSccd)
rc=BleCharDescUserDesc(usrDesc$, mdUsrDsc)

IF rc==0 THEN
  PRINT "\nChar created and User Description '";usrDesc$;"' added"
ELSE
  PRINT "\nFailed"
ENDIF

Expected Output:
Char created and User Description 'A description' added

BLECHARDESCUSERDESC is an extension function.

**BleCharDescPrstnFmt**

**FUNCTION**

This function adds an optional Presentation Format descriptor to a characteristic and can only be called after BleCharNew() has started the process of describing a new characteristic. It adds the descriptor to the GATT table with open read permission and no write access, which means a metadata parameter is not required.

The BT 4.0 specification states that one or more presentation format descriptors can occur in a characteristic and that, if more than one, then an Aggregate Format description is also included.

The book *Bluetooth Low Energy: The Developer’s Handbook* by Robin Heydon, says the following on the subject of the Presentation Format descriptor:

“One of the goals for the Generic Attribute Profile was to enable generic clients. A generic client is defined as a device that can read the values of a characteristic and display them to the user without understanding what they mean.

... The most important aspect that denotes if a characteristic can be used by a generic client is the Characteristic Presentation Format descriptor. If this exists, it’s possible for the generic client to display its value, and it is safe to read this value.”

**BLECHARDESCPRSTNFMT(nFormat, nExponent, nUnit, nNameSpace, nNSdesc)**

    PRINT "\nFailed"
ENDIF

// ~ ~ ~
// other optional descriptors
// ~ ~ ~

// 16 bit signed integer = 0x0E
// exponent = 2
// unit = 0x271A ( amount concentration (mole per cubic metre) )
// namespace = 0x01 == Bluetooth SIG
// description = 0x0000 == unknown
IF BleCharDescPrstnFrmt(0x0E,2,0x271A,0x01,0x0000)==0 THEN
    PRINT "\nPresentation Format Descriptor added"
ELSE
    PRINT "\nPresentation Format Descriptor not added"
ENDIF

Expected Output:

Char created and User Description 'A description' added
Presentation Format Descriptor added

BLECHARDESCPRSTNFRMT is an extension function.
BleCharDescAdd

Note: This function has a bug for firmware versions prior to 1.4.X.Y.

FUNCTION
This function is used to add any characteristic descriptor as long as its UUID is not in the range 0x2900 to 0x2904 inclusive as they are treated specially using dedicated API functions. For example, 0x2904 is the Presentation Format descriptor and it is catered for by the API function BleCharDescPrstnFrmt(). Since this function allows existing/future defined descriptors to be added that may or may not have write access or require security requirements, a metadata object must be supplied allowing that to be configured.

BLECHARDESCADDnUid16, attr$, mdDesc)

Returns INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.

Arguments

<table>
<thead>
<tr>
<th>nUid16</th>
<th>byVal nUid16 AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a value in the range 0x2905 to 0x2999</td>
<td></td>
</tr>
<tr>
<td>Note: This is the actual UUID value, NOT the handle.</td>
<td></td>
</tr>
<tr>
<td>The highest value at the time of writing is 0x2908, defined for the Report Reference Descriptor. See <a href="http://developer.bluetooth.org/gatt/descriptors/Pages/DescriptorsHomePage.aspx">http://developer.bluetooth.org/gatt/descriptors/Pages/DescriptorsHomePage.aspx</a> for a list of descriptors defined and adopted by the Bluetooth SIG.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>attr$</th>
<th>byRef attr$ AS STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is the data that will be saved in the descriptor’s attribute.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>mdDesc</th>
<th>byVal n AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is mandatory metadata that is used to define the properties of the descriptor attribute that is created in the characteristic and was pre-created using the help of the function BleAttrMetaData(). If the write rights are set to one or greater, then the attribute is marked as writable and so the client is to modify the attribute value.</td>
<td></td>
</tr>
</tbody>
</table>

Interactive Command No

DIM mdUsrDsc : mdUsrDsc = charMet
DIM mdSccd : mdSccd = charMet

//initialise char, write/read enabled, accept signed writes, indicatable
```
BLECHARDESCADD is an extension function.

Other descriptors added successfully
**BleCharCommit**

**FUNCTION**

This function commits a characteristic which was prepared by calling BleCharNew() and optionally BleCharDescUserDesc(), BleCharDescPrstnFrmtd() or BleCharDescAdd().

It is an instruction to the GATT table manager that all relevant attributes that make up the characteristic should appear in the GATT table in a single atomic transaction. If it successfully created, a single composite characteristic handle is returned which should not be confused with GATT table attribute handles. If the characteristic is not accepted, then this function returns a non-zero result code which conveys the reason and the handle argument that is returned has a special invalid handle of 0.

The characteristic handle that is returned references an internal opaque object that is a linked list of all the attribute handles in the characteristic which by definition implies that there is a minimum of 1 (for the characteristic value attribute) and more as appropriate. For example, if the characteristic’s property specified is notifiable then a single CCCD attribute also exists.

Please note that in reality, in the GATT table, when a characteristic is registered there are actually a minimum of two attribute handles, one for the characteristic declaration and the other for the value. However, there is no need for the smartBASIC apps developer to access it, so it is not exposed. Access is not required because the characteristic was created by the application developer and so shall already know its content – which never changes once created.

**BLECHARCOMMIT(hService, attr$, charHandle)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>
</tr>
</tbody>
</table>
| **hService** | byVal hService AS INTEGER  
This is the handle of the service that this characteristic belongs to, which in turn was created using the function BleSvcCommit(). |
| **attr$** | byRef attr$ AS STRING  
This string contains the initial value of the value attribute in the characteristic. The content of this string is copied into the GATT table and so the variable can be reused after this function returns. |
| **charHandle** | byRef charHandle AS INTEGER  
The composite handle for the newly created characteristic is returned in this argument. It is zero if the function fails with a non-zero result code. This handle is then used as an argument in subsequent function calls to perform read/write actions, so it is must be placed in a global smartBASIC variable.  
When a significant event occurs as a result of action by a remote client, an event message is sent to the application which can be serviced using a handler. That message contains a handle field corresponding to this composite characteristic handle. Standard procedure is to ‘select’ on that value to determine which characteristic the message is intended for.  
See event messages: EVCHARHVC, EVCHARVAL, EVCHARCCCD, EVCHARSCCD, EVCHARDESC. |

BLECHARVALUEINDICATE is an extension function.

**BleCharDescRead**

**FUNCTION**

This function reads the current content of a writable characteristic descriptor identified by the two parameters supplied in the EVCHARDESC event message after a Gatt client writes to it.

In most cases a local read is performed when a GATT client writes to a characteristic descriptor attribute. The write event is presented asynchronously to the *smart* BASIC application in the form of an EVCHARDESC event and so this function is most often accessed from the handler that services that event.

**BLECHARDESCREAD**

```plaintext
charHandle, nDescHandle, nOffset, nLength, nDescUuidHandle, attr$)
```

- **Returns**
  INTEGER, a result code.  
  Most typical value – 0x0000, indicating a successful operation.

- **Arguments**
  - `charHandle`  
    byVal `charHandle` AS INTEGER  
    This is the handle to the characteristic whose descriptor must be read which was returned when BleCharCommit() was called and is supplied in the EVCHARDESC event message.
  - `nDescHandle`  
    byVal `nDescHandle` AS INTEGER  
    This is an index into an opaque array of descriptor handles inside the charHandle and is supplied as the second parameter in the EVCHARDESC event message.
  - `nOffset`  
    byVal `nOffset` AS INTEGER  
    This is the offset into the descriptor attribute from which the data should be read and copied into attr$.
  - `nLength`  
    byVal `nLength` AS INTEGER  
    This is the number of bytes to read from the descriptor attribute from offset nOffset and copied into attr$.

BLECHARDESCREAD is an extension function.

**GATT Client Functions**

This section describes all functions related to GATT client capability which enables interaction with GATT servers at the other end of the BLE connection. The Bluetooth Specification 4.0 and newer allows for a device to be a GATT server and/or GATT client simultaneously and the fact that a peripheral mode device accepts a connection and in all use cases has a GATT server table does not preclude it from interacting with a GATT table in the central role device which is connected to it.

These GATT client functions allow the developer to discover services, characteristics and descriptors, read and write to characteristics and descriptors and handle either notifications or indications.

To interact with a remote GATT server, it is important to have a good understanding of how it is constructed and the best way is to see it as a table consisting of many rows and three visible columns (handle, type, value) and at least one more column which is not visible but the content affects access to the data column.

<table>
<thead>
<tr>
<th>16-bit Handle</th>
<th>Type (16 or 128 bit)</th>
<th>Value (1 to 512 bytes)</th>
<th>Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0001</td>
<td>0x2800</td>
<td>UUID of the Service</td>
<td>Primary Service 1 Start</td>
</tr>
</tbody>
</table>

These rows are grouped into collections called services and characteristics. The grouping is achieved by creating a row with Type = 0x2800 or 0x2801 for services (primary and secondary respectively) and 0x2803 for characteristics.

Basically, a table should be scanned from top to bottom and the specification stipulates that the 16-bit handle field contains values in the range 1 to 65535 and are in ascending order and gaps are allowed.

When scanning, if a row is encountered with the value 0x2800 or 0x2801 in the Type column then it is understood as the start of a primary or secondary service which in turn contains at least one characteristic or one ‘included service’ which have Type=0x2803 and 0x2802 respectively.

When a row with Type = 0x2803 (a characteristic) is encountered, the next row will contain the value for that characteristic and then after that there may be 0 or more descriptors.

This means each characteristic shall consist of at least two rows in the table, and if descriptors exist for that characteristic, then a single row per descriptor.
<table>
<thead>
<tr>
<th>Handle</th>
<th>Type</th>
<th>Value</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0002</td>
<td>0x2803</td>

</tr>
</tbody>
</table>

A color highlighted example of a GATT server table is shown above which shows there are three services (at handles 0x0001, 0x0008 and 0x000B) because there are three rows where the Type = 0x2803 and all rows up to the next instance of a row with Type=0x2800 or 2801 belong to that service.

In each group of rows for a service, you can see one or more characteristics where Type=0x2803. For example, the service beginning at handle 0x0008 has one characteristic which contains two rows identified by handles 0x0009 and 0x000A and the actual value for the characteristic starting at 0x0009 is in the row identified by 0x000A.

Likewise, each characteristic starts with a row with Type=0x2803 and all rows following it up to a row with type = 0x2800/2801/2803 are considered belonging to that characteristic. For example, see characteristic at row with handle = 0x0004 which has the mandatory value row and then 2 descriptors.

The Bluetooth specification allows for multiple instances of the same service or characteristics or descriptors and they are differentiated by the unique handle. Hence when a handle is known there is no ambiguity.
Each GATT server table will allocate the handle numbers, the only stipulation being that they be in ascending order (gaps are allowed). This is important to understand because two devices containing the same services and characteristic and in EXACTLY the same order may NOT allocate the same handle values, especially if one device increments handles by one and another with some other arbitrary random value. The specification DOES however stipulate that once the handle values are allocated they be fixed for all subsequent connections, unless the device exposes a GATT service which allows for indications to the client that the handle order has changed and thus force it to flush its cache and rescan the GATT table.

When a connection is first established, there is no prior knowledge as to which services exist and of their handles, so the GATT protocol which is used to interact with GATT servers provides procedures that allow for the GATT table to be scanned so that the client can ascertain which services are offered. This section describes smartBASIC functions which encapsulate and manage those procedures to enable a smartBASIC application to map the table.

These helper functions have been written to help gather the handles of all the rows which contain the value type for appropriate characteristics as those are the ones that will be read or written to. The smartBASIC internal engine also maintains data objects so that it is possible to interact with descriptors associated with the characteristic.

In a nutshell, the table scanning process will reveal characteristic handles (as handles of handles) and these are then used in other GATT client related smartBASIC functions to interact with the table to for example read/write or accept and process incoming notifications and indications.

This encapsulated approach is to ensure that the least amount of RAM resource is required to implement a GATT Client and given that these procedures operate at speeds many orders of magnitude slower compared to the speed of the CPU and energy consumption is to be kept as low as possible, the response to a command will be delivered asynchronously as an event for which a handler will have to be specified in the user smartBASIC application.

The rest of this chapter describes all the GATT client commands, responses and events in detail along with example code demonstrating usage and expected output.

Events and Messages

The nature of GATT client operation consists of multiple queries and acting on the responses. Due to the connection intervals being vastly slower than the speed of the CPU, responses can arrive many tens of milliseconds after the procedure was triggered, which are delivered to an application using an event or message. Since these event/messages are tightly coupled with the appropriate commands, all but one is described when the command that triggers them is described.

The event EVGATTCTOUT is applicable for all Gatt client-related functions which result in transactions over the air. The Bluetooth specification states that if an operation is initiated and is not completed within 30 seconds then the connection shall be dropped as no further Gatt Client transaction can be initiated.
**EVATTRWRITE event message**

This event message is thrown if BleGattcWrite() returns a success. The message contains the following three INTEGER parameters:

- Connection handle
- Handle of the attribute
- Gatt status of the write operation.

**Gatt status of the write operation** is one of the following values, where 0 implies the write was successfully expedited.

<table>
<thead>
<tr>

ENDFUNC 1

'==============================================================================
'==============================================================================
FUNCTION HandlerGattcTout(cHndl) AS INTEGER
    PRINT "\nEVGATTCTOUT connHandle=":cHndl
ENDFUNC 1

'==============================================================================
// Main() equivalent
'==============================================================================
ONEVENT EVBLEMSG CALL HndlrBleMsg
OnEvent EVGATTCTOUT call HandlerGattcTout

rc = OnStartup()

WAITEVENT

Expected Output:

...  
...  
EVGATTCTOUT connHandle=123  
...  
...  

**BleGattcOpen**

**FUNCTION**

This function is used to initialize the GATT client functionality for immediate use so that appropriate buffers for caching GATT responses are created in the heap memory. About 300 bytes of RAM is required by the GATT client manager and given that a majority of RM1xx use cases do not use it, the sacrifice of 300 bytes, which is nearly 15% of the available memory, is not worth the permanent allocation of memory.

There are various buffers that need to be created that are needed for scanning a remote GATT table which are of fixed size. There is however, one buffer which can be configured by the smartBASIC apps developer and that is the ring buffer that is used to store incoming notifiable and indicatable characteristics. At the
time of writing this user manual the default minimum size is 64 unless a bigger one is desired and in that
case the input parameter to this function specifies that size. A maximum of 2048 bytes is allowed, but that
can result in unreliable operation as the smartBASIC runtime engine is starved of memory very quickly.

Use SYSINFO(2019) to obtain the actual default size and SYSINFO(2020) to obtain the maximum allowed.
The same information can be obtained in interactive mode using the commands AT I 2019 and 2020
respectively.

Note: When the ring buffer for the notifiable and indicatable characteristics is full, then any new
messages are discarded and depending on the flags parameter the indicates are or are not
confirmed.

This function is safe to call when the GATT client manager is already open, however, in that case the
parameters are ignored and existing values are retained and any existing GATT client operations are not
interrupted.

It is recommended that this function NOT be called when in a connection.

**BLEGATTCOPEN(nNotifyBufLen, nFlags)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>
</tr>
<tr>
<td>nNotifyBufLen byVal nNotifyBufLen AS INTEGER This is the size of the ring buffer used for incoming notifiable and indicatable characteristic data. Set to 0 to use the default size.</td>
<td></td>
</tr>
<tr>
<td>nFlags    byVal nFlags AS INTEGER Bit 0 : Set to 1 to disable automatic indication confirmations if buffer is full then the Handle Value confirmation will only be sent when BleGattcNotifyRead() is called to read the ring buffer. Bit 1..31 : Reserved for future use and must be set to 0s</td>
<td></td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>

</tbody>
</table>

/*Example :: BleGattcOpen.sb (See in RM1xxCodeSnippets.zip)*/

```
DIM rc

//open the gatt client with default notify/indicate ring buffer size
rc = BleGattcOpen(0,0)
IF rc == 0 THEN
    PRINT "\nGatt Client is now open"
ENDIF

//open the client with default notify/indicate ring buffer size - again
rc = BleGattcOpen(128,1)
```
```plaintext
IF rc == 0 THEN
    PRINT "\nGatt Client is still open, because already open"
ENDIF

Expected Output:

<table>
<thead>
<tr>
<th>Gatt Client is now open</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gatt Client is still open, because already open</td>
</tr>
</tbody>
</table>

BLEGATTCOPEN is an extension function.

BleGattcClose

SUBROUTINE

This function is used to close the GATT client manager and is safe to call if it is already closed.

It is recommended that this function is not called when in a connection.

**BLEGATTCLOSE ()**

<table>
<thead>
<tr>
<th>Arguments</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

//Example :: BleGattcClose.sb (See in RM1xxCodeSnippets.zip)

    DIM rc
    //open the gatt client with default notify/indicate ring buffer size
    rc = BleGattcOpen(0,0)
    IF rc == 0 THEN
        PRINT "\nGatt Client is now open"
    ENDIF
    BleGattcClose()
    PRINT "\nGatt Client is now closed"
    BleGattcClose()
    PRINT "\nGatt Client is closed - was safe to call when already closed"
```
Expected Output:

- Gatt Client is now open
- Gatt Client is now closed
- Gatt Client is closed - was safe to call when already closed

BLEGATTCLOSE is an extension subroutine.

**BleDiscServiceFirst/BleDiscServiceNext**

**FUNCTIONS**

This pair of functions is used to scan the remote Gatt server for all primary services with the help of the EVDISCRIMSVIC message event and when called, a handler for the event message **must** be registered as the discovered primary service information is passed back in that message.

A generic or UUID-based scan can be initiated. The former scans for all primary services and the latter scans for a primary service with a particular UUID, the handle of which must be supplied and is generated by using either BleHandleUuid16() or BleHandleUuid128().

While the scan is in progress and waiting for the next piece of data from a GATT server, the module enters low power state as the WAITEVENT statement is used as normal to wait for events and messages.

Depending on the size of the remote GATT server table and the connection interval, the scan of all primary may take many 100s of milliseconds, and while this is in progress it is safe to do other non GATT-related operations such as servicing sensors and displays or any of the onboard peripherals.

**EVDISCRIMSVIC message**

This event message is thrown if either BleDiscServiceFirst() or BleDiscServiceNext() returns a success. The message contains the following four INTEGER parameters:

- Connection Handle
- Service Uuid Handle
- Start Handle of the service in the Gatt Table
- End Handle for the service.

If no more services were discovered because the end of the table was reached, then all parameters contain 0 except for the Connection Handle.

**BLEDISCRISERVICEFIRST**

A typical pseudo code for discovering primary services involves first calling BleDiscServiceFirst(), then waiting for the EVDISCRIMSVIC event message and depending on the information returned in that message calling BleDiscServiceNext(), which in turn results in another EVDISCRIMSVIC event message and typically is as follows:

Register a handler for the EVDISCRIMSVIC event message
On EVDISCPRIMSV event message
   If Start/End Handle == 0 then scan is complete
   Else Process information then
       call BleDiscServiceNext()
       if BleDiscServiceNext() not OK then scan complete

Call BleDiscServiceFirst()
If BleDiscServiceFirst() ok then Wait for EVDISCPRIMSV

---

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. The typical value is 0x0000, indicating a successful operation and it means an EVDISCPRIMSV event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVDISCPRIMSV message is not thrown.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
<th>connHandle</th>
<th>ByVal nConnHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>This is the connection handle as returned in the on-connect event for the connection on which the remote GATT Server can be accessed. This is returned in the EVBLEMSG event message with msgId == 0 and msgCtx has the connection handle.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
<th>startAttrHandle</th>
<th>ByVal startAttrHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>This is the attribute handle from where the scan for primary services starts and you can typically set it to 0 to ensure that the entire remote GATT server is scanned.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
<th>uuidHandle</th>
<th>ByVal uuidHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Set this to 0 if you want to scan for any service, otherwise this value is generated either by BleHandleUuid16() or BleHandleUuid128() or BleHandleUuidSibling().</td>
</tr>
</tbody>
</table>

**BLEDISCERSERVICE_NEXT()**

Calling this assumes that BleDiscServiceFirst() has been called at least once to set up the internal primary services scanning state machine.

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. The typical value is 0x0000, indicating a successful operation and it means an EVDISCPRIMSV event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVDISCPRIMSV message is not thrown.</th>

BLEDISCSEVICESFIRST and BLEDISCSERVICENEXT are both extension functions.
BleDiscCharFirst/BleDiscCharNext

FUNCTIONS

These pair of functions are used to scan the remote GATT server for characteristics in a service with the help of the EVDISCCHAR be registered as the discovered characteristics information is passed back in that message be registered as the discovered characteristics information is passed back in that message be registered as the discovered characteristics information is passed back in that message be registered as the discovered characteristics information is passed back in that message.

A generic or UUID-based scan can be initiated. The former scans for all characteristics and the latter scans for a characteristic with a particular UUID, the handle of which must be supplied and is generated by using either BleHandleUuid16() or BleHandleUuid128().

If instead it is known that a GATT table has a specific service and a specific characteristic, then a more efficient method for locating details of that characteristic is to use the function BleGattcFindChar() which is described later.

While the scan is in progress and waiting for the next piece of data from a GATT server the module enters low power state as the WAITEVENT statement is used as normal to wait for events and messages.

Depending on the size of the remote GATT server table and the connection interval, the scan of all characteristics may take many 100s of milliseconds, and while this is in progress it is safe to do other non-GATT related operations such as servicing sensors and displays or any of the onboard peripherals.

Note: It is not currently possible to scan for characteristics in included services. This is a future enhancement.

EVDISCCHAR event message

This event message is thrown if either BleDiscCharFirst() or BleDiscCharNext() returns a success. The message contains five INTEGER parameters:

- Connection Handle
- Characteristic Uuid Handle
- Characteristic Properties
- Handle for the Value Attribute of the Characteristic
- Included Service Uuid Handle

If no more characteristics were discovered because the end of the table was reached, then all parameters contain 0 apart from the Connection Handle.

‘Characteristic Uuid Handle’ contains the UUID of the characteristic and supplied as a handle.

‘Characteristic Properties’ contains the properties of the characteristic and is a bit mask as follows:

<table>
<thead>
<tr>
<th>Bit 0</th>
<th>Set if BROADCAST is enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 1</td>
<td>Set if READ is enabled</td>
</tr>

‘Handle for the Value Attribute of the Characteristic’ is the handle for the value attribute and is the value to store to keep track of important characteristics in a GATT server for later read/write operations.

‘Included Service Uuid Handle’ is for future use and will always be 0.

**BLEDISCCHARFIRST(charUuidHandle, startAttrHandle, endAttrHandle)**

A typical pseudo code for discovering characteristic involves first calling BleDiscCharFirst() with information obtained from a primary services scan and then waiting for the EVDISCCHAR event message and depending on the information returned in that message calling BleDiscCharNext() which in turn results in another EVDISCCHAR event message and typically is as follows:

```
Register a handler for the EVDISCCHAR event message

On EVDISCCHAR event message
  If Char Value Handle == 0 then scan is complete
  Else Process information then
    call BleDiscCharNext()
    if BleDiscCharNext() not OK then scan complete

Call BleDiscCharFirst( --information from EVDISCPRIMSVC )
If BleDiscCharFirst() ok then Wait for EVDISCCHAR
```

**Returns**

INTEGER, a result code.

Typical value – 0x0000, indicating a successful operation and it means an EVDISCCHAR event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVDISCCHAR message is not thrown.

**Arguments**

<table>
<thead>
<tr>
<th><strong>connHandle</strong></th>
<th>byVal nConnHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is the connection handle as returned in the on-connect event for the connection on which the remote Gatt Server can be accessed. This will have been returned in the EVBLETMSG event message with msgId == 0 and msgCtx will have been the connection handle.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>charUuidHandle</strong></th>
<th>byVal charUuidHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set this to 0 if you want to scan for any characteristic in the service, otherwise this value will have been generated either by BleHandleUuid16() or BleHandleUuid128() or BleHandleUuidSibling().</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>startAttrHandle</strong></th>
<th>byVal startAttrHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is the attribute handle from where the scan for characteristic will be started and will have been acquired by doing a primary services scan, which returns the start and end handles of services.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>endAttrHandle</strong></th>
<th>byVal endAttrHandle AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is the end attribute handle for the scan and will have been acquired by doing a primary services scan, which returns the start and end handles of services.</td>
<td></td>
</tr>
</tbody>
</table>

**Interactive Command**

No
**BLEDISCCHARNEXT)**

Calling this assumes that BleDiscCharFirst() has been called at least once to set up the internal characteristics scanning state machine. It scans for the next characteristic.

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation and it means an EVDISCCHAR event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVDISCCHAR message is not thrown.</th>
</tr>
</thead>
</table>
| Arguments | **connHandle** | byVal nConnHandle AS INTEGER  
This is the connection handle as returned in the on-connect event for the connection on which the remote Gatt Server can be accessed. This will have been returned in the EVBLEMSG event message with msgId == 0 and msgCtx will have been the connection handle. |

Interactive Command: No

Exiting...

BLEDISCCCHARFIRST and BLEDISCCCHARNEXT are both extension functions.
**BleDiscDescFirst/BleDiscDescNext**

**FUNCTIONS**

These functions are used to scan the remote GATT server for descriptors in a characteristic with the help of the EVDISCDESC be registered as the discovered descriptor information is passed back in that. be registered as the discovered descriptor information is passed back in that. be registered as the discovered descriptor information is passed back in that.

A generic or UUID-based scan can be initiated. The former scans for all descriptors and the latter scans for a descriptor with a particular UUID, the handle of which must be supplied and is generated by using either BleHandleUuid16() or BleHandleUuid128().

If a GATT table has a specific service, characteristic and a specific descriptor, then a more efficient method for locating details of that characteristic is to use the function BleGattcFindDesc() which is described later.

While the scan is in progress and waiting for the next piece of data from a GATT server, the module enters low power state as the WAITEVENT statement is used as normal to wait for events and messages.

Depending on the size of the remote GATT server table and the connection interval, the scan of all descriptors may take many 100s of milliseconds, and while this is in progress it is safe to do other non-GATT related operations like for example servicing sensors and displays or any of the onboard peripherals.

**EVDISCDESC event message**

This event message is thrown if either BleDissDescFirst() or BleDiscDescNext() returns a success. The message contains the following three INTEGER parameters:

- Connection Handle
- Descriptor UUID Handle
- Handle for the Descriptor in the remote GATT table

If no more descriptors were discovered because the end of the table was reached, then all parameters contain 0 except the Connection Handle.

‘Descriptor Uuid Handle’ contains the UUID of the descriptor and supplied as a handle.

‘Handle for the Descriptor in the remote GATT table’ is the handle for the descriptor, and also is the value to store to keep track of important characteristics in a GATT server for later read/write operations.

**BLEDISCOSECFIRST(descUuidHandle, charValHandle)**

A typical pseudo code for discovering descriptors involves first calling BleDiscDescFirst() with information obtained from a characteristics scan and then waiting for the EVDISCOSE event message and depending on the information returned in that message calling BleDiscDescNext() which in turn will result in another EVDISCOSE event message and typically is as follows:

```c
// Register a handler for the EVDISCOSE event message

On EVDISCOSE event message
    If Descriptor Handle == 0 then scan is complete
    Else Process information then
```
call BleDiscDescNext()
if BleDiscDescNext() not OK then scan complete

Call BleDiscDescFirst( --information from EVDISCCHAR )
If BleDiscDescFirst() ok then Wait for EVDISCDESC

### BLEDISCDESCNEXT

Calling this assumes that BleDiscCharFirst() has been called at least once to set up the internal characteristics scanning state machine and that BleDiscDescFirst() has been called at least once to start the descriptor discovery process.

**Returns**

INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation it means an EVDISCDESC event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVDISCDESC message is not thrown.

**Arguments**

- **connHandle**
  - byVal nConnHandle AS INTEGER
  - This is the connection handle as returned in the on-connect event for the connection on which the remote Gatt Server can be accessed. This is returned in the EVBLEMSG event message with msgId == 0 and msgCtx is the connection handle.

- **descUuidHandle**
  - byVal descUuidHandle AS INTEGER
  - Set this to 0 if you want to scan for any descriptor in the characteristic, otherwise this value is generated either by BleHandleUuid16() or BleHandleUuid128() or BleHandleUuidSibling().

- **charValHandle**
  - byVal charValHandle AS INTEGER
  - This is the value attribute handle of the characteristic on which the descriptor scan is to be performed. It is acquired from an EVDISCCHAR event.

### BLEDISCDESCFIRST

Calling this assumes that BleDiscDescsDescFirst() has been called at least once to set up the internal characteristics scanning state machine and that BleDiscDescFirst() has been called at least once to start the descriptor discovery process.

**Returns**

INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation it means an EVDISCDESC event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVDISCDESC message is not thrown.

**Arguments**

- **connHandle**
  - byVal nConnHandle AS INTEGER
  - This is the connection handle as returned in the on-connect event for the connection on which the remote Gatt Server can be accessed. This is returned in the EVBLEMSG event message with msgId == 0 and msgCtx is the connection handle.

BLEDISCDESCFIRST and BLEDISCDESCNEXT are both extension functions.
BleGattcFindChar

FUNCTION

This function facilitates a quick and efficient way of locating the details of a characteristic if the UUID is known along with the UUID of the service containing it. The results are delivered in an EVFINDCHAR event of a service with the same UUID. It’s located with index values 3 and 2 respectively.

Given that the results are returned in an event message, a handler must be registered for the EVFINDCHAR event.

Depending on the size of the remote GATT server table and the connection interval, the search of the characteristic may take many 100s of milliseconds, and while this is in progress, it is safe to do other non-GATT-related operations such as servicing sensors and displays or any of the onboard peripherals.

Note: It is not currently possible to scan for characteristics in included services. This will be a future enhancement.

EVFINDCHAR event message

This event message is thrown if BleGattcFindChar() returns a success. The message contains the following four INTEGER parameters:

- Connection Handle
- Characteristic Properties
- Handle for the Value Attribute of the Characteristic
- Included Service UUID Handle

If the specified instance of the service/characteristic is not present in the remote GATT server table, then all parameters will contain 0 except for Connection Handle.

‘Characteristic Properties’ contains the properties of the characteristic and is a bit mask:

| Bit 0 | Set if BROADCAST is enabled |
| Bit 1 | Set if READ is enabled |
| Bit 2 | Set if WRITE_WITHOUT_RESPONSE is enabled |
| Bit 3 | Set if WRITE is enabled |
| Bit 4 | Set if NOTIFY is enabled |
| Bit 5 | Set if INDICATE is enabled |
| Bit 6 | Set if AUTHENTICATED_SIGNED_WRITE is enabled |
| Bit 7 | Set if RELIABLE_WRITE is enabled |
| Bit 15 | Set if the characteristic has extended properties |

‘Handle for the Value Attribute of the Characteristic’ is the handle for the value attribute and is the value to store to keep track of important characteristics in a GATT server for later read/write operations.

‘Included Service UUID Handle’ is for future use and is always 0.
## BLEGATTCFINDCHAR(svcUuidHndl, svcIndex, charUuidHndl, charIndex))

A typical pseudo code for finding a characteristic involves calling BleGattcFindChar() which in turn results in the EVFINDCHAR event message and typically is as follows:

```
Register a handler for the EVFINDCHAR event message
On EVFINDCHAR event message
  If Char Value Handle == 0 then
    Characteristic not found
  Else
    Characteristic has been found
Call BleGattcFindChar()
If BleGattcFindChar() ok then Wait for EVFINDCHAR
```

### Returns
INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation and it means an EVFINDCHAR event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVFINDCHAR message is not thrown.

### Arguments

BLEGATTCFINDCHAR is an extension function.
**BleGattcFindDesc**

**FUNCTION**

This function facilitates a quick and efficient way of locating the details of a descriptor if the UUID is known along with the UUID of the service and the UUID of the characteristic containing it and the results are delivered in an EVFINDDESC event message. If the GATT server table has multiple instances of the same service/characteristic/descriptor combination then this function works; in addition to the UUID handles to be searched for, it accepts instance parameters which are indexed from 0. This means the following:

The second instance of a descriptor in the fourth instance of a characteristic in the third instance of a service (all with the same UUID) are located with index values 1, 3, and 2 respectively.

Given that the results are returned in an event message, a handler **must** be registered for the EVFINDDESC event.

Depending on the size of the remote GATT server table and the connection interval, the search of the characteristic may take many 100s of milliseconds and, while this is in progress, it is safe to do other non GATT related operations such as servicing sensors and displays or any of the onboard peripherals.

---

**Note:** It is not currently possible to scan for characteristics in included services. This is planned for a future release.

---

**EVFINDDESC event message**

This event message is thrown if BleGattcFindDesc() returned a success. The message contains the following INTEGER parameters:

- Connection Handle
- Handle of the Descriptor

If the specified instance of the service/characteristic/descriptor is not present in the remote GATT server table, then all parameters will contain 0 apart from the Connection Handle.

‘Handle of the Descriptor’ is the handle for the descriptor and is the value to store to keep track of important descriptors in a GATT server for later read/write operations – for example CCCD’s to enable notifications and/or indications.

**BLEGATTCFINDDESC**svcUuHndl, svcIdx, charUuHndl, charIdx, descUuHndl, descIdx)

A typical pseudo code for finding a descriptor involves calling BleGattcFindDesc() which in turn will result in the EVFINDDESC event message and typically is as follows:

```plaintext
Register a handler for the EVFINDDESC event message

On EVFINDDESC event message
    If Descriptor Handle == 0 then
        Descriptor not found
    Else
        Descriptor has been found

Call BleGattcFindDesc()
If BleGattcFindDesc() ok then Wait for EVFINDDESC
```
## Returns

INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation and it means an EVFINDDESC event message is thrown by the smartBASIC runtime engine containing the results. A non-zero return value implies an EVFINDDESC message is not thrown.

## Arguments

<table>
<thead>
<tr>

If the handle for an attribute is known, then these functions are used to read the content of that attribute from a specified offset in the array of octets in that attribute value. Given that the success or failure of this read operation is returned in an event message, a handler must be registered for the EVATTRREAD event.
Depending on the connection interval, the read of the attribute may take many 100s of milliseconds, and while this is in progress, it is safe to do other non GATT-related operations such as servicing sensors and displays or any of the onboard peripherals.

BleGattcRead is used to trigger the procedure and BleGattcReadData is used to read the data from the underlying cache when the EVATTRREAD event message is received with a success status.

**EVATTRREAD event message**

This event message is thrown if BleGattcRead() returns a success. The message contains the following INTEGER parameters:
- Connection Handle
- Handle of the Attribute
- GATT status of the read operation

‘**Gatt status of the read operation**’ is one of the following values, where 0 implies the read was successfully expedited and the data can be obtained by calling BlePubGattClientReadData().

</table>
A typical pseudo code for reading the content of an attribute calling BleGattcRead() which in turn will result in the EVATTRREAD event message and typically is as follows:

```plaintext
Register a handler for the EVATTRREAD event message

On EVATTRREAD event message
    If Gatt_Status == 0 then
        BleGattcReadData()  //to actually get the data
    Else
        Attribute could not be read

    Call BleGattcRead()
    If BleGattcRead() ok then Wait for EVATTRREAD
```

**BLEGATTCREADDRATTRHndl, offset))**

This function is used to collect the data from the underlying cache when the EVATTRREAD event message has a success GATT status code.

**Returns**

INTEGER, a result code.
Most typical value – 0x0000, indicating a successful read.

<table>
<thead>
<tr>
<th>Arguments</th>
<th>Description</th>
</tr>
</thead>
</table>
| connHndl   | byVal connHndl AS INTEGER  
This is the connection handle as returned in the on-connect event for the connection on which the remote Gatt Server can be accessed. This will have been returned in the EVBLEMSG event message with msgId == 0 and msgCtx will have been the connection handle. |
| attrHndl   | byVal attrHndl AS INTEGER  
Set this to the handle of the attribute to read and is a value in the range 1 to 65535. |

**BleGattcWrite**

**FUNCTION**

If the handle for an attribute is known, then this function is used to write into an attribute starting at offset 0. The acknowledgement is returned via a EVATTRWRITE event message.

Given that the success or failure of this write operation is returned in an event message, a handler **must** be registered for the EVATTRWRITE event.

Depending on the connection interval, the write to the attribute may take many 100s of milliseconds, and while this is in progress, it is safe to do other non GATT related operations such as servicing sensors and displays or any of the onboard peripherals.

**EVATTRWRITE event message**

The EVATTRWRITE event message **WILL** be thrown if BleGattcWrite() returns a success. It is described in the Events & Message section above.

**BLEGATTWRITEHndl, attrData($)$$**

A typical pseudo code for writing to an attribute which will result in the EVATTRWRITE event message and typically is as follows:

```plaintext
Register a handler for the EVATTRWRITE event message
On EVATTRWRITE event message
  If Gatt_Status == 0 then
    Attribute was written successfully
  Else
    Attribute could not be written
```
Call **BleGattcWrite()**
If BleGattcWrite() ok then Wait for EVATTRWRITE

<table>

BLEGATTWRITE is an extension function.

**BleGattcWriteCmd**

**FUNCTION**

If the handle for an attribute is known, then this function is used to write into an attribute starting at offset 0 when no acknowledgment response is expected. The signal that the command has actually been transmitted and that the remote link layer has acknowledged is by the EVNOTIFYBUF event.

---

**Note:** The acknowledgement received for the BleGattcWrite() command is from the higher level GATT layer, not to be confused with the link layer ACK in this case.

*All packets are acknowledged at link layer level. If a packet fails to get through then that condition will manifest as a connection drop due to the link supervision timeout.*

---

Given that the transmission and link layer ACK of this write operation is indicated in an event message, a handler **must** be registered for the EVNOTIFIBUF event.

Depending on the connection interval, the write to the attribute may take many 100s of milliseconds, and while this is in progress it is safe to do other non GATT-related operations like for example servicing sensors and displays or any of the onboard peripherals.

**EVNOTIFYBUF event**

This event message is thrown if BleGattcWriteCmd() returned a success. The message contains no parameters.
BLEGATTCWRITECMDHndl, attrData$)

A typical pseudo code for writing to an attribute which will result in the EVNOTIFYBUF event is as follows:

```
Register a handler for the EVNOTIFYBUF event message
On EVNOTIFYBUF event message
    Can now send another write command
Call BleGattcWriteCmd()
If BleGattcWrite() ok then Wait for EVNOTIFYBUF
```

**Returns**

INTEGER, a result code.
Most typical value – 0x0000, indicating a successful read.

**Arguments**

<table>
<thead>
<tr>
<th>conHndl</th>
<th>byVal conHndl AS INTEGER</th>
</tr>
</thead>
<tbody>

BLEGATTWRITECMD is an extension function.

**BleGattcNotifyRead**

**FUNCTION**

A GATT Server has the ability to notify or indicate the value attribute of a characteristic when enabled via the Client Characteristic Configuration Descriptor (CCCD). This means data arrives from a GATT server at any time and has to be managed so that it can be synchronized with the smartBASIC runtime engine.

Data arriving via a notification does not require GATT acknowledgements, however indications require them. This GATT client manager saves data arriving via a notification in the same ring buffer for later extraction using the command BleGattcNotifyRead() and for indications an automatic GATT acknowledgement is sent when the data is saved in the ring buffer. This acknowledgment happens even if the data was discarded because the ring buffer was full. If, however, it is required that the data NOT be acknowledged when it is discarded on a full buffer, then set the flags parameter in the BleGattcOpen() function where the GATT client manager is opened.

In the case when an ACK is NOT sent on data discard, the GATT server is throttled and so no further data is notified or indicated by it until BleGattcNotifyRead() is called to extract data from the ring buffer to create space and it triggers a delayed acknowledgement.
When the GATT client manager is opened using BleGattcOpen() it is possible to specify the size of the ring buffer. If a value of 0 is supplied, then a default size is created. SYSINFO(2019) in a smartBASIC application or the interactive mode command AT I 2019 returns the default size. Likewise, SYSINFO(2020) or the command AT I 2020 returns the maximum size.

Data that arrives via notifications or indications get stored in the ring buffer and at the same time a EVATTRNOTIFY runtime engine. This is an event, in the same way an incoming UART receive character generates an event, that is, no data payload is attached to the event.

**EVATTRNOTIFY event message**

This event is thrown when a notification or an indication arrives from a GATT server. The event contains no parameters. Please note that if one notification/indication arrives or many, like in the case of UART events, the same event mask bit is asserted. The paradigm being that the smartBASIC application is informed that it needs to go and service the ring buffer using the function BleGattcNotifyRead.

**BLEGATTCNOTIFYREADHndl, attrData$, discardCount])**

A typical pseudo code for handling and accessing notification/indication data is as follows:

```plaintext
Register a handler for the EVATTRNOTIFY event message

On EVATTRNOTIFY event
BLEGATTCNOTIFYREADHndl, attrData$, discardCount)
Process the data

Enable notifications and/or indications via CCCD descriptors
```

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful read.</th>
</tr>
</thead>
</table>
| Arguments| **connHndl** | byVal connHndl AS INTEGER  
This is the connection handle as returned in the on-connect event for the connection on which the remote GATT server can be accessed. This is returned in the EVBLEMSG event message with msgId == 0 and msgCtx is the connection handle. |
|          | **attrHndl** | byVal attrHndl AS INTEGER  
The handle for the attribute that is to be written to. |
|          | **attrData$** | byRef attrData$ AS STRING  
The attribute data to write. |
|          | **discardedCount** | byRef discardedCount AS INTEGER  
On exit this should contain 0 and it signifies the total number of notifications or indications that got discarded because the ring buffer in the GATT client manager is full. If non-zero values are encountered, it is recommended that the ring buffer size be increased by using BleGattcClose() when the GATT client is opened using BleGattcOpen(). |

BLEGATTNCNOTIFYREAD is an extension function.

**Attribute Encoding Functions**

Data for characteristics are stored in Value attributes, arrays of bytes. Multibyte Characteristic Descriptors content is stored similarly. Those bytes are manipulated in *smart* BASIC applications using STRING variables.

The Bluetooth specification stipulates that multibyte data entities are stored communicated in little endian format and so all data manipulation is done similarly. Little endian means that a multibyte data entity is stored so that lowest significant byte is position at the lowest memory address and likewise when transported, the lowest byte gets on the wire first.

This section describes all the encoding functions which allow those strings to be written to in smaller bytewise subfields in a more efficient manner compared to the generic STRXXX functions that are made available in *smart* BASIC.

**Note:** CCCD and SCCD Descriptors are special cases; they have two bytes which are treated as 16 bit integers. This is reflected in *smart*BASIC applications so that INTEGER variables are used to manipulate those values instead of STRINGS.
### BleEncode8

**FUNCTION**

This function overwrites a single byte in a string at a specified offset. If the string is not long enough, then it is extended with the new extended block uninitialized and then the byte specified is overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum attribute length can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

#### BLEENCODE8 (attr$, nData, nIndex)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Arguments</strong></td>
<td></td>
</tr>
</tbody>
</table>
| `attr$` | byRef `attr$` AS STRING  
This argument is the string that is written to an attribute |
| `nData` | byVal `nData` AS INTEGER  
The least significant byte of this integer is saved. The rest is ignored. |
| `nIndex` | byVal `nIndex` AS INTEGER  
This is the zero-based index into the string `attr$` where the new fragment of data is written. If the string `attr$` is not long enough to accommodate the index plus the length of the fragment, it is extended. If the extended length exceeds the maximum allowable length of an attribute (see SYSINFO(2013)), this function fails. |

**Interactive Command**

No

```powershell
//Example :: BleEncode8.sb (See in RM1xxCodeSnippets.zip)

DIM rc
DIM attr$

attr$="Laird"

PRINT "\nattr$=";attr$

//Remember: - 4 bytes are used to store an integer on the RM1xx

//write 'C' to index 2 -- '111' will be ignored
rc=BleEncode8(attr$,0x11143,2)
//write 'A' to index 0
rc=BleEncode8(attr$,0x41,0)
//write 'B' to index 1
```
BLEencode8 is an extension function.

**BleEncode16**

**FUNCTION**

This function overwrites two bytes in a string at a specified offset. If the string is not long enough, then it is extended with the new extended block uninitialized and then the bytes specified are overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum attribute length can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

BLEENCODE16 is an extension function.

BleEncode24

FUNCTION

This function overwrites three bytes in a string at a specified offset. If the string is not long enough, then it is extended with the new extended block uninitialized and then the bytes specified are overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum attribute length can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

BLEENCODE24 (attr$,$nData, nIndex)

Returns
INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.

Arguments
attr$ byRef attr$ AS STRING
This argument is the string that is written to an attribute.

nData byVal nData AS INTEGER
The three least significant bytes of this integer is saved. The rest is ignored.

nIndex byVal nIndex AS INTEGER
This is the zero based index into the string attr$ where the new fragment of data is written. If the string attr$ is not long enough to accommodate the index plus the length of the fragment, it is extended. If the extended length exceeds the maximum allowable length of an attribute (see SYSINFO(2013)), this function fails.

</tr>
</thead>
<tbody>
<tr>
<td>The four bytes of this integer is saved. The rest is ignored.</td>
<td></td>
</tr>
</tbody>
</table>
**nIndex**

**byVal nIndex AS INTEGER**

This is the zero based index into the string attr$ where the new fragment of data is written. If the string attr$ is not long enough to accommodate the index plus the length of the fragment, it is extended. If the extended length exceeds the maximum allowable length of an attribute (see SYSINFO(2013)), this function fails.

### Interactive Command

No

```plaintext
//Example :: BleEncode32.sb (See in RM1xxCodeSnippets.zip)

DIM rc
DIM attr$ : attr$="Laird"

//write 'BCDE' to index 1
rc=BleEncode32(attr$,0x45444342,1)

//write 'A' to index 0
rc=BleEncode8(attr$,0x41,0)

PRINT "attr$=";attr$
```

**Expected Output:**

```
attr$=ABCDE
```

BLEENCODE32 is an extension function.

**BleEncodeFLOAT**

**FUNCTION**

This function overwrites four bytes in a string at a specified offset. If the string is not long enough, it is extended with the new extended block uninitialized and then the byte specified is overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum attribute length can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

**BLEENCODEFLOAT (attr$, nMatissa, nExponent, nIndex)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
</table>
| Arguments | **attr$$**  
**byRef attr$$ AS STRING** This argument is the string that is written to an attribute. |
### nMantissa

**byVal nMantissa**  AS INTEGER

This value must be in the range -8388600 to +8388600 or the function fails. The data is written in little endian so that the least significant byte is at the lower memory address. Note that the range is not +/- 2048 because after encoding the following two byte values have special meaning:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x07FFFFFF</td>
<td>NaN (Not a Number)</td>
</tr>
<tr>
<td>0x08000000</td>
<td>NRes (Not at this resolution)</td>
</tr>
<tr>
<td>0x07FFFFFE</td>
<td>+ INFINITY</td>
</tr>
<tr>
<td>0x08000002</td>
<td>- INFINITY</td>
</tr>
<tr>
<td>0x08000001</td>
<td>Reserved for future use</td>
</tr>
</tbody>
</table>

### nExponent

**byVal nExponent**  AS INTEGER

This value must be in the range -128 to 127 or the function fails.

### nIndex

**byVal nIndex**  AS INTEGER

This is the zero based index into the string attr$ where the new fragment of data is written. If the string attr$ is not long enough to accommodate the index plus the length of the fragment, it is extended. If the extended length exceeds the maximum allowable length of an attribute (see SYSINFO(2013)), this function fails.

### Interactive Command

No

---

//Example :: BleEncodeFloat.sb (See in RM1xxCodeSnippets.zip)

```basic
DIM rc
DIM attr$ : attr$=""

//write 1234567 x 10^-54 as FLOAT to index 2
PRINT BleEncodeFLOAT(attr$,123456,-54,0)

//write 1234567 x 10^1000 as FLOAT to index 2 and it will fail
//because the exponent is too large, it has to be < 127
IF BleEncodeFLOAT(attr$,1234567,1000,2) !=0 THEN
  PRINT "\nFailed to encode to FLOAT"
ENDIF

//write 10000000 x 10^0 as FLOAT to index 2 and it will fail
//because the mantissa is too large, it has to be < 8388600
IF BleEncodeFLOAT(attr$,10000000,0,2) !=0 THEN
  PRINT "\nFailed to encode to FLOAT"
ENDIF```
BLENCODEFLOAT is an extension function.

**BleEncodeSFloatEx**

**FUNCTION**

This function overwrites two bytes in a string at a specified offset as short 16-bit float value. If the string is not long enough, it is extended with the extended block uninitialized. Then the bytes are overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum attribute length can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

**BLENCODESFLOATEX (attr$, nData, nIndex)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>
</tr>
</tbody>
</table>
| attr$  | byRef attr$  AS STRING  
This argument is the string that is written to an attribute. |
| nData | byVal nData  AS INTEGER  
The 32-bit value is converted into a 2-byte IEEE-11073 16 bit SFLOAT consisting of a 12-bit signed mantissa and a 4-bit signed exponent. This means a signed 32-bit value always fits in such a FLOAT entity, but there is loss in significance to 12 from 32. |
| nIndex | byVal nIndex  AS INTEGER  
This is the zero based index into the string attr$ where the new fragment of data is written. If the string attr$ is not long enough to accommodate the index plus the length of the fragment, it is extended. If the new length exceeds the maximum allowable length of an attribute (see SYSINFO(2013)), this function fails. |
| Interactive Command | No |

//Example :: BleEncodeSFloatEx.sb (See in RM1xxCodeSnippets.zip)

```plaintext
DIM rc, mantissa, exp
DIM attr$ : attr$=""

//write 2,147,483,647 as SFLOAT to index 0
rc=BleEncodeSFloatEx(attr$,2147483647,0)
```
BLEENCODESFLOAT is an extension function.

**BleEncodeSFLOAT**

**FUNCTION**

This function overwrites two bytes in a string at a specified offset as short 16-bit float value. If the string is not long enough, it is extended with the new block uninitialized. Then the byte specified is overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum attribute length can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

Expected Output:

Success
Failed to encode to SFLOAT
Failed to encode to SFLOAT

BLEENCODESFLOAT is an extension function.

BleEncodeTIMESTAMP

FUNCTION

This function overwrites a 7-byte string into the string at a specified offset. If the string is not long enough, it is extended with the new extended block uninitialized and then the byte specified is overwritten.

The 7-byte string consists of a byte each for century, year, month, day, hour, minute and second. If (year * month) is zero, it is taken as “not noted” year and all the other fields are set to zero (not noted).

For example, 5 May 2013 10:31:24 is represented as \14\0D\05\05\0A\1F\18

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum length of an attribute as implemented can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.

Note: When the attr$ string variable is updated, the two-byte year field is converted into a 16-bit integer. Hence \14\0D gets converted to \DD\07
### BLEENCODETIMESTAMP (attr$, timestamp$, nIndex)

**Returns**

INTEGER, a result code.  
Most typical value – 0x0000, indicating a successful operation.

**Arguments**

<table>
<thead>
<tr>
<th>attr$</th>
<th>byRef attr$ AS STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This argument is the string that is written to an attribute.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>timestamp$</th>
<th>byRef timestamp$ AS STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This is an exactly 7-byte string as described above. For example, 5 May 2013 10:31:24 is entered \14\0D\05\05\0A\1F\18</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>nIndex</th>
<th>byVal nIndex AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This is the zero based index into the string attr$ where the new fragment of data is written. If the string attr$ is not long enough to accommodate the index plus the length of the fragment it is extended. If the new length exceeds the maximum allowable length of an attribute (see SYSINFO(2013)), this function fails.</td>
</tr>
</tbody>
</table>

**Interactive Command**

No

#### Example:

```basic
//Example :: BleEncodeTimestamp.sb (See in RM1xxCodeSnippets.zip)

DIM rc, ts$
DIM attr$ : attr$=""

//write the timestamp <5 May 2013 10:31:24>

    ts$="\14\0D\05\05\0A\1F\18"

PRINT BleEncodeTimestamp(attr$,ts$,0)
```

**Expected Output:**

0

BLEENCODETIMESTAMP is an extension function.

### BleEncodeSTRING

**FUNCTION**

This function overwrites a substring at a specified offset with data from another substring of a string. If the destination string is not long enough, it is extended with the new block uninitialized. Then the byte is overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails. The maximum length of an attribute as implemented can be obtained using the function SYSINFO(n) where n is 2013. The Bluetooth specification allows a length between 1 and 512.
BleEncodeSTRING (attr$, nIndex1, str$, nIndex2, nLen)

Returns
INTEGER, a result code.
Most typical value – 0x0000, indicating a successful operation.

Arguments
attr$ byRef attr$ AS STRING
This argument is the string that is written to an attribute

nIndex1 byVal nIndex1 AS INTEGER
This is the zero based index into the string attr$ where the new fragment of data is written. If
the string attr$ is not long enough to accommodate the index plus the length of the fragment it
is extended. If the new length exceeds the maximum allowable length of an attribute (see
SYSINFO(2013)), this function fails.

str$ byRef str$ AS STRING
This contains the source data which is qualified by the nIndex2 and nLen arguments that follow.

nIndex2 byVal nIndex2 AS INTEGER
This is the zero based index into the string str$ from which data is copied. No data is copied if
this is negative or greater than the string.

nLen byVal nLen AS INTEGER
This species the number of bytes from offset nIndex2 to be copied into the destination string. It
is clipped to the number of bytes left to copy after the index.

Interactive Command
No

//Example :: BleEncodeString.sb (See in RM1xxCodeSnippets.zip)
DIM rc, attr$, ts$ : ts$="Hello World"
//write "Wor" from "Hello World" to the attribute at index 2
rc=BleEncodeString(attr$,2,ts$,6,3)
PRINT attr$

Expected Output:
\00\00Wor

BLEENCODESTRING is an extension function.

BleEncodeBITS

FUNCTION
This function overwrites some bits of a string at a specified bit offset with data from an integer which is
treated as a bit array of length 32. If the destination string is not long enough, it is extended with the new
extended block uninitialized. Then the bits specified are overwritten.

If the nIndex is such that the new string length exceeds the maximum attribute length, this function fails.
The maximum length of an attribute as implemented can be obtained using the function SYSINFO(n)
where \( n \) is 2013. The Bluetooth specification allows a length between 1 and 512; hence the \((nDstIdx + nBitLen)\) cannot be greater than the max attribute length times 8.

**BleEncodeBITS** \( (\text{attr}, nDstIdx, \text{srcBitArr}, nSrcIdx, nBitLen) \)

| Returns | INTEGER, a result code.  
Most typical value – 0x0000, indicating a successful operation. |
|---------|-------------------------------------------------|

<table>
<thead>
<tr>
<th>Arguments</th>
<th></th>
</tr>
</thead>
</table>
| attr$     | byRef \( \text{attr$} \) AS STRING  
This is the string written to an attribute. It is treated as a bit array. |
| nDstIdx   | byVal \( nDstIdx \) AS INTEGER  
This is the zero based bit index into the string \( \text{attr$} \), treated as a bit array, where the new  
fragment of data bits is written. If the string \( \text{attr$} \) is not long enough to accommodate the index  
plus the length of the fragment it is extended. If the new length exceeds the maximum  
allowable length of an attribute (see SYSINFO(2013)), this function fails. |
| srcBitArr | byVal \( \text{srcBitArr} \) AS INTEGER  
This contains the source data bits which is qualified by the \( nSrcIdx \) and \( nBitLen \) arguments that follow. |
| nSrcIdx   | byVal \( nSrcIdx \) AS INTEGER  
This is the zero based bit index into the bit array contained in \( \text{srcBitArr} \) from where the data bits are  
copied. No data is copied if this index is negative or greater than 32. |
| nBitLen   | byVal \( nBitLen \) AS INTEGER  
This species the number of bits from offset \( nSrcIdx \) to be copied into the destination bit array represented  
by the string \( \text{attr$} \). It is clipped to the number of bits left to copy after the index \( nSrcIdx \). |

Interactive Command

No

```plaintext
//Example :: BleEncodeBits.sb (See in RM1xxCodeSnippets.zip)  
DIM attr$, rc, bA: bA=b'1110100001111  
rc=BleEncodeBits(attr$,20,bA,7,5): PRINT attr$ //copy 5 bits from index 7 to attr$
```

Expected Output:

```
\00\00\A0\01
```

BLEENCODEBITSfunction.function.function.function.function.function.function.

**Attribute Decoding Functions**

Data in a characteristic is stored in a Value attribute, a byte array. Multibyte Characteristic Descriptors  
content are stored similarly. Those bytes are manipulated in \textit{smart}BASIC applications using STRING  
variables.

Attribute data is stored in little endian format.

This section describes decoding functions that allow attribute strings to be read from smaller bytewise  
subfields more efficiently than the generic STRXXXX functions that are made available in \textit{smart} BASIC.
**Note:** CCCD and SCCD descriptors are special cases as they are defined as having just two bytes which are treated as 16 bit integers mapped to INTEGER variables in smartBASIC.

---

### BleDecodeS8

**FUNCTION**

This function reads a single byte in a string at a specified offset into a 32bit integer variable with sign extension. If the offset points beyond the end of the string, then this function fails and returns zero.

**BleDecodeS8 (attr$, nData, nIndex)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, the number of bytes extracted from the attribute string. Can be less than the size expected if the nIndex parameter is positioned towards the end of the string.</th>
</tr>
</thead>
</table>
| Arguments | **attr$**  byRef attr$ AS STRING  
This references the attribute string from which the function reads.  

**nData**  byRef nData AS INTEGER  
This references an integer to be updated with the 8-bit data from attr$, after sign extension.  

**nIndex**  byVal nIndex AS INTEGER  
This is the zero based index into the string attr$ from which the data is read. If the string attr$ is not long enough to accommodate the index plus the number of bytes to read, this function fails. |
| Interactive Command | No |

---

```plaintext
//Example :: BleDecodeS8.sb (See in RM1xxCodeSnippets.zip)

DIM chrHandle, v1, svcHandle, rc
DIM mdVal : mdVal = BleAttrMetadata(1, 1, 50, 0, rc)
DIM attr$: attr$= "\00\01\02\03\04\05\06\07\08\09"
DIM uuid : uuid = 0x1853

//create random service just for this example
rc=BleSvcCommit(1, BleHandleUuid16(uuid), svcHandle)

//create char and commit as part of service commited above
rc=BleCharNew(0x07, BleHandleUuid16(0x2A1C), mdVal, 0, 0)
rc=BleCharCommit(svcHandle, attr$, chrHandle)
rc=BleCharValueRead(chrHandle, attr$)

//read signed byte from index 2
```

**BleDecodeFLOAT**

**FUNCTION**

This function reads four bytes in a string at a specified offset into a couple of 32-bit integer variables. The decoding results in two variables, the 24-bit signed mantissa and the 8-bit signed exponent. If the offset points beyond the end of the string, this function fails.

**BLEDECODEFLOAT (attr$, nMantissa, nExponent, nIndex)**

**Returns**

INTEGER, the number of bytes extracted from the attribute string. Can be less than the size expected if the nIndex parameter is positioned towards the end of the string.

**Arguments**

<table>
<thead>
<tr>
<th>attr$</th>
<th>byRef attr$ AS STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>This references the attribute string from which the function reads.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>nMantissa</th>
<th>byRef nMantissa AS INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is updated with the 24-bit mantissa from the 4-byte object.</td>
<td></td>
</tr>
</tbody>
</table>
If nExponent is 0, you MUST check for the following special values:

<table>
<thead>
<tr>
<th>Hex Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x07FFFFFF</td>
<td>NaN (Not a Number)</td>
</tr>
<tr>
<td>0x08000000</td>
<td>NRes (Not at this resolution)</td>
</tr>
<tr>
<td>0x07FFFFFE</td>
<td>+ INFINITY</td>
</tr>
<tr>
<td>0x08000002</td>
<td>- INFINITY</td>
</tr>
<tr>
<td>0x08000001</td>
<td>Reserved for future use</td>
</tr>
</tbody>
</table>

**nExponent**

byRef nExponent  AS INTEGER

This is updated with the 8-bit mantissa. If it is zero, check nMantissa for special cases as stated above.

** nIndex**

byVal nIndex  AS INTEGER

This is the zero based index into the string attr$ from which data is read. If the string attr$ is not long enough to accommodate the index plus the number of bytes to read, this function fails.

---

```vi
//Example :: BleDecodeFloat.sb (See in RM1xxCodeSnippets.zip)

DIM chrHandle,v1,svcHandle,rc, mantissa, exp
DIM mdVal : mdVal = BleAttrMetadata(1,1,50,0,rc)
DIM attr$ : attr$="\00\01\02\03\04\85\86\87\88\89"
DIM uuid : uuid = 0x1853

rc=BleSvcCommit(1, BleHandleUuid16(uuid),svcHandle)
rc=BleCharNew(0x07,BleHandleUuid16(0x2A1C),mdVal,0,0)
rc=BleCharCommit(svcHandle,attr$,chrHandle)

rc=BleCharValueRead(chrHandle,attr$)

//read 4 bytes FLOAT from index 2 in the string
rc=BleDecodeFloat(attr$,mantissa,exp,2)
PRINT "\nThe number read is ";mantissa;" x 10^";exp

//read 4 bytes FLOAT from index 6 in the string
rc=BleDecodeFloat(attr$,mantissa,exp,6)
PRINT "\nThe number read is ";mantissa;" x 10^";exp
```
BLEDECODEFLOAT is an extension function.

**BleDecodeSFLOAT**

**FUNCTION**

This function reads two bytes in a string at a specified offset into a couple of 32bit integer variables. The decoding results in two variables, the 12-bit signed mantissa and the 4-bit signed exponent. If the offset points beyond the end of the string, then this function fails.

**BLEDECODESFLOAT** (attr$, nMatissa, nExponent, nIndex)

**Returns**

INTEGER, the number of bytes extracted from the attribute string. Can be less than the size expected if the nIndex parameter is positioned towards the end of the string.

**Arguments**

<table>
<thead>
<tr>
<th>attr$</th>
<th>byRef attr$ AS STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>This references the attribute string from which the function reads.</td>
<td></td>
</tr>
</tbody>

<tbody>
<tr>
<td>This is the zero based index into the string attr$ from which data is read. If the string attr$ is not long enough to accommodate the index plus the number of bytes to read, this function fails.</td>
<td></td>
</tr>
</tbody>
</table>

**Interactive Command**

No

//Example :: BleDecodeSFLOAT.sb (See in RM1xxCodeSnippets.zip)

```
DIM chrHandle,v1,svcHandle,rc, mantissa, exp
DIM mdVal : mdVal = BleAttrMetadata (1,1,50,0,rc)
DIM attr$: attr$="\00\01\02\03\04\85\86\87\88\89"
DIM uuid : uuid = 0x1853
```
BLEDECODESFLOAT is an extension function.

** BleDecodeTIMESTAMP **

** FUNCTION **

This function reads seven bytes from string an offset into an attribute string. If the offset plus seven bytes points beyond the end of the string, then this function fails.

The seven-byte string consists of a byte each for century, year, month, day, hour, minute and second. If (year * month) is zero, it is taken as “not noted” year and all the other fields are set to zero (not noted).

For example, 5 May 2013 10:31:24 is represented in the source as \1154\107\05\05\0A\1F\18 and the year is translated into a century and year so that the destination string is \114\0D\05\05\0A\1F\18.

** BLEDECODETIMESTAMP (attr$, timestamp$, nIndex) **

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, the number of bytes extracted from the attribute string. Can be less than the size expected if the nIndex parameter is positioned towards the end of the string.</th>
</tr>
</thead>
</table>
| ** Arguments ** | ** attr$ ** byRef attr$ AS STRING  
This references the attribute string from which the function reads.  
 ** timestamp$ ** byRef timestamp$ AS STRING  
On exit this is an exact 7-byte string as described above. For example, 5 May 2013 10:31:24 is stored as \114\0D\05\05\0A\1F\18. |
**BleDecodeSTRING**

**FUNCTION**

This function reads a maximum number of bytes from an attribute string at a specified offset into a destination string. This function doesn’t fail because the output string can take truncated strings.

**BLEDECODESTRING (attr$, nIndex, dst$, nMaxBytes)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, the number of bytes extracted from the attribute string. Can be less than the size expected if the nindex parameter is positioned towards the end of the string.</th>
</tr>
</thead>
</table>

**Example:**

```vbnet
//Example :: BleDecodeTimestamp.sb (See in RM1xxCodeSnippets.zip)

DIM chrHandle, v1, svcHandle, rc, ts$
DIM mdVal : mdVal = BleAttrMetadata(1,1,50,0,rc)

//5th May 2013, 10:31:24
DIM attr$ : attr$="\00\01\02\DD\07\05\0A\1F\18"
DIM uuid : uuid = 0x1853

rc=BleSvcCommit(1, BleHandleUuid16(uuid), svcHandle)
rc=BleCharNew(0x07,BleHandleUuid16(0x2A1C),mdVal,0,0)
rc=BleCharCommit(svcHandle,attr$,chrHandle)

rc=BleCharValueRead(chrHandle,attr$)

//read 7 byte timestamp from the index 3 in the string
rc=BleDecodeTimestamp(attr$,ts$,3)
PRINT "\nTimestamp = "; StrHexize$(ts$)
```

**Expected Output:**

```
Timestamp = 140D05050A1F18
```
This references the attribute string from which the function reads.

This is the zero based index into string attr$ from which data is read.

This argument is a reference to a string that is updated with up to nMaxBytes of data from the index specified. A shorter string is returned if there are not enough bytes beyond the index.

This specifies the maximum number of bytes to read from attr$.

//Example :: BleDecodeString.sb (See in RM1xxCodeSnippets.zip)

DIM chrHandle,v1,svcHandle,rc, ts$,decStr$
DIM mdVal : mdVal = BleAttrMetadata(1,1,50,0,rc)

"ABCDEFGHIJKLMNOPQRSTUVWXYZ"
DIM attr$ : attr$="41\42\43\44\45\46\47\48\49\4A"
DIM uuid : uuid = 0x1853

rc=BleSvcCommit(1, BleHandleUuid16(uuid),svcHandle)
rc=BleCharNew(0x07,BleHandleUuid16(0x2A1C),mdVal,0,0)
rc=BleCharCommit(svcHandle,attr$,chrHandle)
rc=BleCharValueRead(chrHandle,attr$)

//read max 4 bytes from index 3 in the string
rc=BleDecodeSTRING(attr$,3,decStr$,4)
PRINT "$nd$=";decStr$

//read max 20 bytes from index 3 in the string - will be truncated
rc=BleDecodeSTRING(attr$,3,decStr$,20)
PRINT "$nd$=";decStr$

//read max 4 bytes from index 14 in the string - nothing at index 14
rc=BleDecodeSTRING(attr$,14,decStr$,4)
PRINT "$nd$=";decStr$
BLEDECODESTRING is an extension function.

BleDecodeBits

FUNCTION

This function reads bits from an attribute string at a specified offset (treated as a bit array) into a destination integer object (treated as a bit array of fixed size of 32). This implies a maximum of 32 bits can be read. This function doesn’t fail because the output bit array can take truncated bit blocks.

BLEDECODEBITS (attr$, nSrcIdx, dstBitArr, nDstIdx, nMaxBits)

Returns

INTEGER, the number of bits extracted from the attribute string. Can be less than the size expected if the nSrcIdx parameter is positioned towards the end of the source string or if nDstIdx will not allow more to be copied.

Arguments

attr$ byRef attr$ AS STRING
This references the attribute string from which to read, treated as a bit array. Hence a string of 10 bytes will be an array of 80 bits.

nSrcIdx byVal nSrcIdx AS INTEGER
This is the zero based bit index into the string attr$ from which data is read. For example: the third bit in the second byte is index number 10.

dstBitArr byRef dstBitArr AS INTEGER
This argument references an integer treated as an array of 32 bits into which data is copied. Only the written bits are modified.

nDstIdx byVal nDstIdx AS INTEGER
This is the zero based bit index into the bit array dstBitArr where the data is written to.

nMaxBits byVal nMaxBits AS INTEGER
This argument specifies the maximum number of bits to read from attr$. Due to the destination being an integer variable, it cannot be greater than 32. Negative values are treated as zero.

Interactive Command

No

//Example :: BleDecodeBits.sb (See in RM1xxCodeSnippets.zip)

DIM chrHandle,v1,svcHandle,rc, ts$,decStr$
DIM ba : ba=0
DIM mdVal : mdVal = BleAttrMetadata(1,1,50,0,rc)
BLEDECODEBITS is an extension function.

### Pairing/Bonding Functions

This section describes all functions related to the pairing and bonding manager which manages trusted devices. The database stores information like the address of the trusted device along with the security keys. At the time of writing this manual a maximum of 16 devices can be stored in the database and the command AT I 2012 or at runtime SYSINFO(2012) returns the maximum number of devices that can be saved in the database.
The type of information that can be stored for a trusted device is:

- The MAC address of the trusted device (and it will be the non-resolvable address if the connection was originally established by the central device using its resolvable key – like iOS devices).
- A 16-byte key, eDIV and eRAND for the long term key, called LTK. Up to 2 instances of this LTK can be stored. One which is supplied by the central device and the other is the one supplied by the peripheral. This means in a connection, the device will check which role (peripheral or central) it is connected as and pick the appropriate key for subsequent encryption requests.
- The size of the long term key.
- A flag to indicate if the LTK is authenticated – Man-In-The-Middle (MITM) protection.
- A 16-byte Identity Resolving Key (IRK).
- A 16-byte Connection Signature Resolving Key (CSRK)

**Bonding Table Types: Rolling & Persist**

The bonding database contains two tables of bonds where both tables have the same structure in terms of what each record can store and from a BLE perspective are equal in meaning.

For the purpose of clarity both in this manual and in smartBASIC, one table is called the ‘Rolling’ table and the other is called ‘Persist’ table.

When a new bonding occurs the information is ALWAYS guaranteed to be saved in the ‘Rolling’ table, and if it is full, then the oldest ‘Rolling’ bond is automatically deleted to make space for the new one.

The ‘Persist’ table can only be populated by transferring a bond from the ‘Rolling’ table using the function BleBondingPersistKey.

Use the function BleBondingEraseKey to delete a key and the function will look for it in both tables and when found delete it. There is no need to know which table it belongs to when deleting. The database manager ensures there is only one instance of a bond and so a device cannot occur in both.

The total number of bonds in the ‘Rolling’ and ‘Persist’ tables will always be less than or equal to the capacity of the database which is returned as explained above using AT I 2012 or SYSINFO(2012).

The number of ‘Rolling’ or ‘Persist’ bonds (or maximum capacity) at any time can be obtained by calling the function BleBondingStats. The ‘Persist’ total is the difference between the ‘total’ and ‘rolling’ variables returned by that routine.

At any time, the capacity of the ‘Rolling’ table is the difference between the absolute total capacity and the number of bonds in the ‘Persist’ table. See the function BleBondingStats which returns information that can be used to determine this.

Bonds in the ‘Rolling’ table can be transferred to ‘Persist’ unless the ‘Persist’ table is full. The capacity of the ‘Persist’ table is returned by AT I 2043 or SYSINFO(2043) and at the time of writing this manual it is 12, which corresponds to 75% of the total capacity.

If a bond exists and it happens to be in the ‘Persist’ table and new bonding provides new information, then the record is updated.

If a bond exists and it happens to be in the ‘Rolling’ table and new bonding provides new information then the record is updated and in addition, the age list is updated to that the device is marked the ‘youngest’ in the age list.
A smartBASIC application wanting to manage trusted device will use a combination of the functions: BleBondMngrGetInfo, BleBondingIsTrusted, BleBondingPersistKey and BleBondingEraseKey.

**Whisper Mode Pairing**

BLE provides for simple secure pairing with or without man-in-the-middle attack protection. To enhance security while a pairing is in progress the specification has provided for Out-of-Band pairing where the shared secret information is exchanged by means other than the Bluetooth connection. That mode of pairing is currently not exposed.

Laird have provided an additional mechanism for bonding using the standard inbuilt simple secure pairing which is called Whisper Mode pairing. In this mode, when a pairing is detected to be in progress, the transmit power is automatically reduced so that the ‘bubble’ of influence is reduced and thus a proximity based enhanced security is achieved.

To take advantage of this pairing mechanism, use the function BleTxPwrWhilePairing() to reduce the transmit power for the short duration that the pairing is in progress.

Tests have shown that setting a power of -55 using BleTxPwrWhilePairing() will create a ‘bubble’ of about 30cm radius, outside which pairing will not succeed. This will be reduced even further if the module is in a case which affects radio transmissions.

**BleBondingStats**

**FUNCTION**

This function retrieves statistics of the bonding manager which consists of the total capacity as the return value and the rolling and total bonds via the arguments. By implication, the number of persistent bonds is the difference between nTotal and nRolling.

**BLEBONDINGSTATS (nRolling, nTotal)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER; The maximum capacity of the bonding manager</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>
</tr>
<tr>
<td>nRolling</td>
<td>byRef nRolling AS INTEGER</td>
</tr>
<tr>
<td></td>
<td>On exit this will contain the number of rolling bonds in the database.</td>
</tr>
<tr>
<td>nTotal</td>
<td>byRef nTotal AS INTEGER</td>
</tr>
<tr>
<td></td>
<td>On exit this will contain the total number of bonds in the database.</td>
</tr>
</tbody>
</table>

**Interactive Command**

No

```//Example
DIM rolling, capacity, total
capacity = BleBondingStats(rolling,total)

PRINT "\nCapacity :";capacity
PRINT "\nRolling :";rolling
PRINT "\nTotal :";total
```
Expected Output:

<table>
<thead>
<tr>
<th>Capacity</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rolling</td>
<td>2</td>
</tr>
<tr>
<td>Total</td>
<td>5</td>
</tr>
</tbody>
</table>

BLEBONDINGSTATS is an extension function.

**BleBondingEraseKey**

**FUNCTION**

This function is used to erase the bonding information for a device identified by a Bluetooth address.

If the device does not exist in the database, the function will return a success result code.

**BLEBONDINGERASEKEY (addr$)**

Returns: INTEGER, a result code.
Typical value: 0x0000 (indicates a successful operation)

Arguments:

- **addr$**
  - byRef addr$ AS STRING
  - This is the address of the device for which the bonding information is to be erased

Interactive Command: No

//Example
DIM rc, addr$
addr$="00\00\16\A4\12\34\56"
rc = BleBondingEraseKey(addr$)

BLEBONDINGERASEKey is an extension function.

**BleBondingEraseAll**

**FUNCTION**

This function deletes the entire trusted device database. Other values of the parameter are reserved for future use.

**Note:** In Interactive Mode, the command AT+BTD* can also be used to delete the database.

**BLEBONDINGERASEALL ()**

Arguments: None

Interactive Command: No
BLEBONDINGERASEALL is an extension function.

**BleBondMngrErase**

This subroutine has been deprecated and remains for old apps. New apps should use the function BleBondingEraseAll.

**BleBondingPersistKey**

**FUNCTION**

This function is used to mark a device in the bonding manager as persistent which means it is not automatically deleted if there is no space to store a new bonding. This device can only be deleted using BleBondingEraseAll() or BleBondingEraseKey().

**BLEBONDINGPERISTKEY (addr$)**

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Typical value:</strong></td>
<td>0x0000 (indicates a successful operation)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Arguments</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><em>addr</em>$</td>
<td>byRef $addr$ AS STRING</td>
</tr>
</tbody>
</table>

This is the address of the device for which the bonding information is to be marked as persistent

| Interactive Command | No |

//Example

```plaintext
DIM rc, addr$
addr$="00\00\16\A4\12\34\56"
rc = BleBondingPersistKey(addr$)
```

BLEBONDINGPERISTKEY is an extension function.

**BleBondingIsTrusted**

**FUNCTION**

This function is used to check if a device identified by the address is a trusted device which means it exists in the bonding database.
BLEBONDINGISTRUSTED (addr$, fAsCentral, keyInfo, rollingAge, rollingCount)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER: Is 0 if not trusted, otherwise it is the length of the long term key (LTK)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td></td>
</tr>
</tbody>
</table>
| addr$ | byRef addr$ AS STRING  
This is the address of the device for which the bonding information is to be checked. |
| fAsCentral | Set to 0 if the device is to be trusted as a peripheral and non-zero if to be trusted as central. |
| keyInfo | This is a bit mask with bit meanings as follows:  
This specifies the write rights and shall have one of the following values:  
| Bit 0 | Set if MITM is authenticated |
| Bit 1 | Set if it is a rolling bond and can be automatically deleted if the database is full and a new bonding occurs |
| Bit 2 | Set if an IRK (identity resolving key) exists |
| Bit 3 | Set if a CSRK (connection signing resolving key) exists |
| Bit 4 | Set if LTK as slave exists |
| Bit 5 | Set if LTK as master exists |
| rollingAge | If the value is <= 0 then this is not a rolling device  
1 implies it is the newest bond  
2 implies it is the second newest bond etc. |
| rollingCount | On exit this will contain the total number of rolling bonds. Which give a sense of how old this device is compared to other bonds in the rolling group. |
| Interactive Command | No |

//Example
DIM rc, addr$
addr$="\00\00\16\A4\12\34\56"
rc = BleBondingPersistKey(addr$)

BLEBONDINGISTRUSTED is an extension function.

**BleBondMngrGetInfo**

**FUNCTION**

This function retrieves the MAC address and other information from the trusted device database via an index.

**Note:** Do not rely on a device in the database mapping to a static index. New bondings change the position in the database.
BLEBONDMMGRGETINFO (nIndex, addr$, nExtraInfo)

Returns
INTEGER, a result code.
Typical value: 0x0000 (indicates a successful operation)

Arguments

nIndex
byVal nIndex  AS INTEGER
This is an index in the range 0 to 1, less than the value returned by SYSINFO(2012).

addr$
byRef addr$  AS STRING
On exit, if nIndex points to a valid entry in the database, this variable contains a MAC address exactly seven bytes long. The first byte identifies public or private random address. The next six bytes are the address.

nExtraInfo
byRef nExtraInfo  AS INTEGER
On exit if nIndex points to a valid entry in the database, this variable contains a bitmask where the bits indicate as follows:

| Bit 0..15 | Opaque value and no meaning is to be attached to this |
| Bit 16   | Set if the IRK (identity resolving key) exists |
| Bit 17   | Set if the CSRK (Connection signing resolution key) exists |
| Bit 18   | Set if the LTK ‘as slave’ exists |
| Bit 19   | Set if the LTK ‘as master’ exists |
| Bit 20   | Set if this is rolling bond |

Interactive Command
No

//Example :: BleBondMngrGetInfo.sb
#define BLE_INV_INDEX 24619
DIM rc, addr$, exInfo
rc = BleBondMngrGetInfo(0,addr$,exInfo) //Extract info of device at index 1

IF rc==0 THEN
    PRINT "\nMAC address: \n";addr$
    PRINT "\nInfo: \n";exInfo
ELSEIF rc==BLE_INV_INDEX THEN
    PRINT "\nInvalid index"
ENDIF

Expected Output when valid entry present in database:

MAC address: \00\BC\B1\F3x3\AB
Info: 97457
BLEBONDMDGRINFO is an extension function.

6. LoRa Extensions Built-in Routines

The following commands are specific to the LoRa functionality of the RM1xx.

**LoRaMACSleepMode**

**FUNCTION**

This command places the LoRa chipset in ultra-low power sleep mode. This closes the SPI driver and places the chipset in an unusable state. LORAMACReset must be called prior to re-using the LoRa device.

**LORAMACSleepMode()**

<table>
<thead>
<tr>
<th>Returns</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments: None</td>
<td></td>
</tr>
<tr>
<td>Interactive Command</td>
<td>No</td>
</tr>
</tbody>
</table>

```plaintext
rc = LORAMACSleepMode()
```

LORAMACSleepMode is an extension function.

**LORAMACJoin**

**FUNCTION**

This command begins the Join process to connect to a LoRa gateway device. Before actioning the Join, the module will revert back to its default state, specifically with respect to the data rate, Tx power and, in the case of the RM186, the available frequency channels. All the appropriate network parameters must be configured using the AT+CFGEX commands prior to making this call.

There are two possible Join options:

- **OTA** – where the RM1xx sends IDs to the server and both ends of the link use these IDs to calculate the NwkSKey and the AppSKey that are used in the encryption and decryption of the subsequent data packets.
- **Personalization** – where both the RM1xx and server are preconfigured with the keys NwkSKey, AppSKey and the DevAddr

For more information on the Join options, refer to the Interfacing with LoRaWAN application notes which are available from the Laird RM1xx product page.

If the OTA option is selected, once the LORAMACJoin command is sent an EVLORAMACJOINING event is thrown.

Then on successful completion of the process the EVLORAMACJOINED event will be thrown.
# LORAMACJoin (nFlags)

| Returns | 0x0000 = Successfully started Join process  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0xnnnn = resultCode</td>
</tr>
</tbody>
</table>

## Arguments:

| nFlags | ByVal nFlags INTEGER  
|--------|-------------------------------------------------|
|        | LORAMAC_JOIN_BY_REQUEST  
|        | LORAMAC_JOIN_BY_PERSONALIZATION |

## Interactive Command: None

```plaintext
rc = LORAMACJoin(LORAMAC_JOIN_BY_REQUEST);
#define LORAMAC_JOIN_BY_REQUEST                  1 // Used with LORAMACJoin
#define LORAMAC_JOIN_BY_PERSONALIZATION          0 // Used with LORAMACJoin

DIM rc

FUNCTION LoramacJoining() As Integer
  print "\nJoining"
endfunc 1

FUNCTION LoramacJoined() As Integer
  print "\nJoined"
endfunc 1

ONEVENT EVLORAMACJOINING CALL LoramacJoining
ONEVENT EVLORAMACJOINED CALL LoramacJoined

rc = LORAMACJoin(LORAMAC_JOIN_BY_REQUEST)

WAITEVENT
```

LORAMACJoin is an extension function.

### LORAMACLinkCheck

**FUNCTION**

This command sends a link check request upstream to the gateway. When a link check response is received from the gateway device, a EVLORAMACLINKCHECKRESPMSG message is sent to the application. This message contains two 8-bit values. The first represents the gateway's link margin, in dB, of the last successfully received link check request. The second represents the number of gateways that successfully received the last link check request.

#### LORAMACLinkCheck ()

| Returns | 0x0000 = Successfully sent a LoRa Link Check request message upstream  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0xnnnn = resultCode</td>
</tr>
</tbody>
</table>

## Interactive Command: None
LORAMACLinkCheck is an extension function.

**LORAMACTxData**

**FUNCTION**
This command sends data upstream to the LoRa gateway on the specified port.

**Note:** Port 0 is reserved for MAC commands between the gateway and the end node.

**LORAMACTxData (nPort, Data$, nFlags)**

| Returns          | 0x0000: Successfully queued data for upstream transmission  
|------------------|--------------------------------------------------------------
|                  | 0xnnnn: resultCode                                           |

**Arguments:**

- **nPort**    
  **ByVal nPort INTEGER**
  The port to be used by the transmission.

- **Data$**  
  **ByRef data$ STRING**
  The data to be sent upstream.

- **nFlags**  
  **ByVal nFlags INTEGER**
  Bit mask for options.
  - 0 – Do not request confirmation
  - 1 – Request confirmation

**Interactive Command**

No

```plaintext
DIM data$

FUNCTION LoramacRxComplete() As Integer
  print "\nRx sequence completed "
endfunc 1

FUNCTION LoramacTxComplete() As Integer
  print "\nTx sequence completed "
endfunc 1

ONEVENT EVLORAMACTXCOMPLETE CALL LoramacTxComplete
ONEVENT EVLORAMACRXCOMPLETE CALL LoramacRxComplete

data$ = “foo”
```
//Send a confirmed packet upstream to port 1
LORAMACTxAData(1, data$, 1)

LORAMACTxAData is an extension function.

LORAMACRxData

FUNCTION

This function returns downlink data received from the LoRa gateway. It should only be called from the EVLORAMACRXDATA event handler.

LORAMACRxData (stData$, pRxRSSI, pRxPort, pRxSNR)

<table>
<thead>
<tr>
<th>Returns</th>
<th>0x0000: Success</th>
</tr>
</thead>
</table>

**Arguments:**

<table>
<thead>
<tr>
<th>stData$</th>
<th>ByRef stData$ STRING</th>
<th>The data read from the received packet.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pRxRSSI</td>
<td>ByRef pRxRSSI INTEGER</td>
<td>The RSSI value of the received packet.</td>
</tr>
<tr>
<td>pRxPort</td>
<td>ByRef pRxPort INTEGER</td>
<td>The port on which the packet was received.</td>
</tr>
<tr>
<td>pRxSNR</td>
<td>ByRef pRxSNR INTEGER</td>
<td>The SNR value of the received packet.</td>
</tr>
</tbody>
</table>

**Interactive Command**: No

//==========================================================================
// This handler is called when downlink data is received from the gateway
//==========================================================================
function HandlerLoRaRxData() as integer
  dim data$
  dim nRSSI,nPort,nSNR
  rc = LORAMACRxData(data$, nRSSI, nPort, nSNR)
  print "LoRa Received downstream data on port ";nPort;"\nRSSI: ";nRSSI;" SNR: ";nSNR;"\n";data$;"\n"endfunc 1
OnEvent EVLORAMACRXDATA call HandlerLoRaRxData

LORAMACRxData is an extension function.

LORAMACGetOption

FUNCTION

This function retrieves the value for a specified option.

**Note**: A list of options and their descriptions can be found in RM1xx-defs.h as well as in Table 2.
### LORAMACGetOption (nOptID, optValue$)

**Returns**  
0x0000: Successfully retrieved option value  
0xnnnn: Result code

**Arguments:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| nOptID       | ByVal nOptID INTEGER  
The Option ID as defined in TargetRM1xx-defs.h |
| optValue$    | ByRef optValue$ STRING  
The string in which to return the option value. |

**Interactive Command**  
No

```vbscript
//Example Code
dim reg
dim stringVal$
dim rc

// Retrieve the current data rate and print it
rc = LORAMACGetOption(LORAMAC_OPT_DATA_RATE, stringVal$)
print stringVal$
```

LORAMACGetOption is an extension function.

### LORAMACSetOption

**FUNCTION**

This function sets the value for a specified option.

**Note:** A list of options and their descriptions can be found in RM1xx-defs.h as well as in [Table 2](#).

**LORAMACSetOption (nOptID, optValue$)**

**Returns**  
0x0000: Successfully set option value  
0xnnnn: Result code

**Arguments:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| nOptID       | ByVal nOptID INTEGER  
The Option ID as defined in TargetRM1xx-defs.h |
| optValue$    | ByRef optValue$ STRING  
The value to set. |

**Interactive Command**  
No

```vbscript
//Set the data rate to 5
temp$ = "5"
rc = LORAMACSetOption(LORAMAC_OPT_DATA_RATE, temp$)
```

LORAMACSetOption is an extension function.
LORAMAC Option List

These options are available for use with the LORAMACGetOption and LORAMACSetOption (as specified in the Get and Set columns. Enumerations of these options can be found in RM1xx-defs.h.

Table 2: LORAMAC Option List

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Get</th>
<th>Set</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LORAMAC_OPT_JOIN_STATE</td>
<td>YES</td>
<td>NO</td>
<td>LoRaWAN network joined attribute</td>
</tr>
<tr>
<td>LORAMAC_OPT_DEV_ADDR</td>
<td>YES</td>
<td>YES</td>
<td>The end-device address</td>
</tr>
<tr>
<td>LORAMAC_OPT_DATA_RATE</td>
<td>YES</td>
<td>YES</td>
<td>The data rate of the LoRa radio. Valid values are 0 to 5 for the RM186 and 0 to 4 for the RM191.</td>
</tr>
<tr>
<td>LORAMAC_OPT_TX_POWER</td>
<td>YES</td>
<td>YES</td>
<td>The output power in dB of the LoRa radio. The value entered must be one of the values specified in the LoRaWAN specification. For the RM186 valid values are 2, 5, 8, 11, 14 and 20dBm and for the RM191 10 to 30dBm in 2dBm steps. If an invalid value is entered, then the code will set the power to the nearest value lower than the one entered. Note that the RM1xx is limited to a maximum output power of 13dBm. If a value higher than that is entered the code will automatically limit the power.</td>

</table>

**LORAMACSetDebug**

This command should only be used during development. It is not recommended that this command is left active in any production version of a smartBASIC application.

**FUNCTION**

This function sets the module up to output certain debug information, either as a text string or as a waveform.

**LORAMACSetDebug (nDebug, nTxSio, nRxSio)**

| Returns                      | 0x0000: Successfully actioned command  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments:</td>
<td></td>
</tr>
<tr>
<td>nDebug</td>
<td>ByVal nDebug INTEGER</td>
</tr>
<tr>
<td></td>
<td>0 – Disables debug mode</td>
</tr>
<tr>
<td></td>
<td>1 – Enables debug mode</td>
</tr>
<tr>
<td>nTxSio</td>
<td>ByVal nTxSio INTEGER</td>
</tr>
<tr>
<td></td>
<td>The SIO pin that the Tx waveform is output on.</td>
</tr>
<tr>
<td>nRxSio</td>
<td>ByVal nRxSio INTEGER</td>
</tr>
<tr>
<td></td>
<td>The SIO pin that the Rx waveform is output on.</td>
</tr>
</tbody>
</table>

If debug mode is enabled the module will output the frequency that a packet will be transmitted on and the data rate of that packet when transmitting and the spreading factor and the symbols timeout when receiving.

It will also output 2 waveforms, on the selected SIOs, that mark when the module is in transmit or receive mode.

TxSio and RxSio cannot be the same value unless debug mode is being disabled.

Debug mode is not persisted. If debug mode was enabled and the module was then reset, it would boot up with debug mode disabled.
Setting RM191 ChannelsMask

Note that this section is only relevant to the RM191 modules. The setting of the ChannelsMask in the RM186 is handled completely differently and requires no input by the user.

The RM191 has 64 available 125kHz upstream channels (channels 0-63) starting at 902.3MHz and incrementing linearly in 200kHz steps up to 914.9MHz. There are also 8 500kHz upstream channels (channels 64-71) starting at 903MHz and incrementing linearly in 1.6MHz steps up to 914.2MHz.

Channels are enabled by setting the bit that corresponds to their channel number in a hex string that is either loaded during boot up from a default value or from a value stored in Flash using the at+cfgex 1009 command.

The value that needs to be set is governed by what frequency channels the gateway or gateways you wish to communicate with have been configured for, and for that you will have to consult your network administrator.

For example, the Multitech gateways are configured by selecting one of a series of 8 channel sub-bands, each containing 8x125kHz channels and 1x500kHz channel. So sub-band 1 consists of channels 0-7 and channel 64, sub-band 2 of channels 8-15 and channel 65, up to sub-band 8 which consists of channels 56-63 and channel 71.

The RM191 will default to sub-band 1, however if a different configuration is required then you can set the required channels as show below

<table>
<thead>
<tr>
<th>Sub-Band</th>
<th>Frequency Range (MHz)</th>
<th>Channels</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>902.3–903.7</td>
<td>0-7</td>
<td>at+cfgex 1009 &quot;000100000000000000ff&quot;</td>
</tr>
<tr>
<td>2</td>
<td>903.9–905.3</td>
<td>8-15</td>
<td>at+cfgex 1009 &quot;00020000000000ff00&quot;</td>
</tr>
<tr>
<td>3</td>
<td>905.5–906.9</td>
<td>16-23</td>
<td>at+cfgex 1009 &quot;00040000000000ff0000&quot;</td>
</tr>
<tr>
<td>4</td>
<td>907.1–908.5</td>
<td>24-31</td>
<td>at+cfgex 1009 &quot;000800000000ff0000&quot;</td>
</tr>
<tr>
<td>5</td>
<td>908.7–910.1</td>
<td>32-39</td>
<td>at+cfgex 1009 &quot;001000000000ff000000&quot;</td>
</tr>
<tr>
<td>6</td>
<td>910.3–911.7</td>
<td>40-47</td>
<td>at+cfgex 1009 &quot;0020000000ff000000&quot;</td>
</tr>
<tr>
<td>7</td>
<td>911.9–913.3</td>
<td>48-55</td>
<td>at+cfgex 1009 &quot;004000ff0000000000&quot;</td>
</tr>
<tr>
<td>8</td>
<td>915.5–914.9</td>
<td>56-63</td>
<td>at+cfgex 1009 &quot;0080ff000000000000&quot;</td>
</tr>
<tr>
<td>All bands</td>
<td>902.3–914.9</td>
<td>0-63</td>
<td>at+cfgex 1009 &quot;0fffffff0000000000&quot;</td>
</tr>
</tbody>
</table>

So in the table above, channel 0 would be the least significant bit on the extreme right hand side of the string.

The “All Bands” option would be used if you didn’t know the configuration of a gateway. With this ChannelsMask the RM191 would continue to transmit a packet on random channels until it found one that worked. This would be repeated every packet. So there could be many failed transmissions for each packet.

Most gateways at present only support the “1 side-band” option as this is determined by the configuration of the SX1301 module. However, if a gateway contains more than one of these modules then it is simply
a case of enabling the extra bits. For example, to enable sub-bands 1 and 4 the following string would be entered.

\texttt{at+cfgex 1009 “0009000000000ff0000ff”}

Whilst it is possible to set the hex string to any channel configuration, the present method of configuring the gateways means that the ChannelsMask will most likely be grouped in bands of 3, 4 or 5 channels. For example, if a gateway supported channels 4-7, 28-31 and 67 then the following string would be required

\texttt{at+cfgex 1009 “000800000000f00000ff0”}

Note that the 500kHz channel must fit in one of the 125kHz channel sub-bands.

However, again, it is important to stress that you must contact your network administrator to determine which settings you require.

As has previously been mentioned the \texttt{at+cfgex 1009 “xxx...”} command is stored in flash and the module must be configured before running a smartBASIC application. However it is also possible to modify the channels mask from a smartBASIC application using the \texttt{LoramacSetOption(LORAMAC_OPT_CHANNELMASK,xxx...)}.

So if you wanted to set the RM191 to sub-band 2 then you could enter:

\texttt{LoramacSetOption(LORAMAC_OPT_CHANNELMASK, 000200000000000ff0000)}

Note with this method you do not require the “” around the hex string. Channels Masks entered this way are not persisted. When the module reboots it will revert back to the stored or default value.

Events and Messages

\textbf{EVLORAMACJOINING}

The device has started the Over-the-Air (OTA) Join procedure. A Join Request message will be sent and the device will await the Join Response message from the server.

\textbf{EVLORAMACJOINED}

The device successfully completed the Join procedure. If using the OTA Join procedure, this indicates that a successful Join Response message was received from the server. This event will be thrown immediately when joining the network using Activation by Personalization (ABP).

\textbf{EVLORAMACJOINFAILED}

The Join procedure failed.

\textbf{EVLORAMACTXCOMPLETE}

The device is no longer trying to send data upstream.

\textbf{EVLORAMACRESET}

The SX1272 device has been reset.
EVLORAMACRXCOMPLETE
The device successfully received a LoRa packet with payload data.

EVLORAMACTXTIMEOUT
An ACK was not received for a confirmed uplink message

EVLORAMACRXTIMEOUT
A timeout occurred waiting for a downlink message.

EVLORAMACRXERROR
An error occurred in the receive path.

EVLORAMACRXDATA
Downstream data received from the gateway. The data can be read by the application using LORAMACRxData().

EVLORAMACLINKCHECKRESPMSG
This message is returned from the LoRa stack when a Link Check response is received from a LoRa gateway. The demodulation margin is reported as an 8-bit unsigned integer named Margin which ranges from 0 to 254. Margin indicates the link margin in dB of the last successfully reported LinkCheckReq command. The gateway count is returned as a variable named GwCnt and represents the number of gateways that successfully received the last LinkCheckReq command. See section 5.1 of the LoRaWAN specification for more details.

EVLORAMACTXDONE
This event indicates that a packet has successfully been transmitted from the radio. It is this event that all subsequent receive windows are timed with respect to.

EVLORAMACNOSYNC
This event indicates that the receiver has failed to detect a sync message from the gateway during a receive window and so has exited the receive state. As there can be 2 potential receive windows for every transmitted packet, in worse case scenarios there can be two of these events for every uplink packet.

EVLORAMACADR
This event indicates that the RM1xx has received an ADR command from the gateway/server and that a parameter setting on the module could have changed. The parameters that this command can change are the TxPower, Data rate or ChannelsMask.
7. OTHER EXTENSION BUILT-IN Routines

This chapter describes non BLE-related extension routines that are not part of the core smartBASIC language.

System Configuration Routines

SystemStateSet

FUNCTION

This function is used to alter the power state of the module as per the input parameter.

SYSTEMSTATESET (nNewState)

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, a result code. Most typical value – 0x0000, indicating a successful operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>ByVal nNewState AS INTEGER</td>
</tr>
<tr>
<td>nNewState</td>
<td>New state of the module as follows:</td>
</tr>
<tr>
<td></td>
<td>0 System OFF (Deep Sleep Mode)</td>
</tr>
<tr>
<td>Note:</td>
<td>You may also enter this state when UART is open and a BREAK condition is asserted.</td>
</tr>
<tr>
<td></td>
<td>Deasserting BREAK makes the module resume through reset i.e. power cycle.</td>
</tr>
</tbody>
</table>

Interactive
Command

No

//Example :: SystemStateSet.sb (See in RM1xxCodeSnippets.zip)

//Put the module into deep sleep
PRINT "\n"; SystemStateSet(0)

SYSTEMSTATESET is an extension function.

Miscellaneous Routines

ReadPwrSupplyMv

FUNCTION

This function is used to read the power supply voltage and the value will be returned in millivolts.

READPWRSUPPLYMV ()

<table>
<thead>
<tr>
<th>Returns</th>
<th>INTEGER, the power supply voltage in millivolts.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>None</td>
</tr>
<tr>
<td>Interactive</td>
<td>No</td>
</tr>
</tbody>
</table>

Command

//Example :: ReadPwrSupplyMv.sb (See in RM1xxCodeSnippets.zip)
//read and print the supply voltage
PRINT "\nSupply voltage is "; ReadPwrSupplyMv();"mV"

Expected Output:
Supply voltage is 3343mV

READPWRSUPPLYMV is an extension function.

SetPwrSupplyThreshMv

FUNCTION
This function sets a supply voltage threshold. If the supply voltage drops below this, then the BLE_EVMSG event is thrown into the run time engine with a MSG ID of BLE_EVBLEMSGID_POWER_FAILURE_WARNING (19) and the context data will be the current voltage in millivolts.

Events and Messages

<table>
<thead>
<tr>
<th>MsgId</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>19</td>
<td>The supply voltage has dropped below the value specified as the argument to this function in the most recent call. The context data is the current reading of the supply voltage in millivolts</td>
</tr>
</tbody>
</table>

SETPWRSUPPLYTHRESHMV)

Returns
INTEGER, 0 if the threshold is successfully set, 0x6605 if the value cannot be implemented.

Arguments
nThreshMv byVal nThresMv AS INTEGER
The BLE_EVMSG event is thrown to the engine if the supply voltage drops below this value. Valid values are 2100, 2300, 2500 and 2700.

Interactive Command
No
//Example :: SetPwrSupplyThreshMv.sb (See in RM1xxCodeSnippets.zip)
DIM rc
DIM mv

//==============================================================================
// Handler for generic BLE messages
//==============================================================================
FUNCTION HandlerBleMsg(BYVAL nMsgId, BYVAL nCtx) AS INTEGER
    SELECT nMsgId
    CASE 19
        PRINT "\n --- Power Fail Warning ",nCtx
        //mv=ReadPwrSupplyMv()
        PRINT "\n --- Supply voltage is "; ReadPwrSupplyMv();"mV"
    CASE ELSE
        //ignore this message
    ENDSELECT
ENDFUNC 1

//==============================================================================
// Handler to service button 0 pressed
//==============================================================================
FUNCTION HndlrBtn0Pr() AS INTEGER
    //just exit and stop waiting for events
ENDFUNC 0

ONEVENT EVBLEMSG CALL HandlerBleMsg
ONEVENT EVGPIOCHAN1 CALL HndlrBtn0Pr

rc=GpioBindEvent(1,16,1)     //Channel 1, bind to low transition on GPIO pin 16
PRINT "\nSupply voltage is "; ReadPwrSupplyMv();"mV"
mv=2700
rc=SetPwrSupplyThreshMv(mv)

PRINT "\nWaiting for power supply to fall below ";mv;"mV"

//wait for events and messages
WAITEVENT
Expected Output:

```
Supply voltage is 3343mV
Waiting for power supply to fall below 2700mV
Exiting...
```

SETPWRSUPPLYTHRESHMV is an extension function.

8. EVENTS AND MESSAGES

smart BASIC is designed to be event driven, which makes it suitable for embedded platforms where it is normal to wait for something to happen and then respond.

To ensure that access to variables and resources ends up in race conditions, the event handling is done synchronously, meaning the smart BASIC runtime engine has to process a WAITEVENT statement for any events or messages to be processed. This guarantees that smart BASIC will never need the complexity of locking variables and objects.

There are many subsystems which generate events and messages as follows:

- Timer events, which generate timer expiry events and are described here.
- Messages thrown from within the user’s BASIC application as described here.
- Events related to the UART interface as described here.
- GPIO input level change events as described here.
- BLE events and messages as described here.
- Generic Characteristics events and messages as described here.

9. MODULE CONFIGURATION

There are many features of the module that cannot be modified programmatically which relate to interactive mode operation or alter the behavior of the smartBASIC runtime engine. These configuration objects are stored in non-volatile flash and are retained until the flash file system is erased via AT&F* or AT&F 1.

To write to these objects, which are identified by a positive integer number, the module must be in interactive mode and the command AT+CFG must be used which is described in detail here.

To read current values of these objects use the command AT+CFG, described here.

Predefined configuration objects are as listed under details of the AT+CFG command.
10. MISCELLANEOUS

Bluetooth Result Codes

There are some operations and events that provide a single byte Bluetooth HCI result code, e.g. the EVDISCON message. The meaning of the result code is as per the list reproduced from the Bluetooth Specifications below. No guarantee is supplied as to its accuracy. Consult the specification for more.

Result codes in grey are not relevant to Bluetooth Low Energy operation and are unlikely to appear.

11. ACKNOWLEDGEMENTS

The following are required acknowledgements to address our use of open source code on the RM1xx to implement AES encryption.

Laird’s implementation includes the following files: aes.c and aes.h.

This software is provided ‘as is’ with no explicit or implied warranties in respect of its properties, including, but not limited to, correctness and/or fitness for purpose.

Issue 09/09/2006

This is an AES implementation that uses only 8-bit byte operations on the cipher state (there are options to use 32-bit types if available).

The combination of mix columns and byte substitution used here is based on that developed by Karl Malbrain. His contribution is acknowledged.
## INDEX OF smartBASIC COMMANDS

| AT + BTD *                        | 10, 11 |
| AT + MAC                         | 10    |
